Abstract: *Matrix metalloproteinases (MMPs) are a member of the protein family intimately associated with zinc-containing endopeptidases, which are the main proteases implicated in extracellular matrix (ECM) degradation. The high ability of MMPs in the degradation of extracellular proteins is an important event in many normal biological as well as pathologic processes, including tumor progression, tissue repair, wound healing, developmental morphogenesis, and inflammatory diseases. This review is focused on the description of the modulation mechanism of MMPs via oncoviruses. Up to now, a large number of oncogenic viruses have been detected and recognized as etiologic factors of multiple human cancers. Actually, by expression of several viral oncoproteins of tumorigenic viruses with the simple genetic system, we are able to deregulate or modulate the pathways of cell transformation procedure in malignancy. In brief, upregulated expression of MMPs genes by direct (through DNA binding) , as well as indirect interactions (by activating PI-3K/AKT, ERK/MAPK, IFN/JAK/STAT, JNK, NF-κB signaling pathways and/or immune response) with tumorigenic viruses, have a noticeable role in the proliferation of cells, as well as angiogenesis, mobility, EMT, invasiveness, and metastatic features. In fact, the growth of tumor-related researchers offers a future perspective for the efficiency of targeted, molecular-based therapies and its anticancer effects via diverse mechanisms such as the suppression of viral oncoproteins.*

Keywords: *Matrix Metalloproteinases (MMPs), Tumor Viruses, Tumor Progression*

INTRODUCTION

Matrix metalloproteinases (MMPs), form a family of zinc-dependent extracellular matrix (ECM) remodeling endopeptidase enzymes that play a role in a number of physiological processes, like the healing of wounds, organismal development, and effectors of immune responses, as well as in pathological conditions, like pulmonary dysfunctions, autoimmune diseases, and cancer [1,2]. To date, almost 25 various vertebrate MMPs have been recognized, including 23 members in humans [3]. Based on sequence homology and specificity for substrate, the MMPs family divides into six categories of stromelysins, collagenases, matrilysins, gelatinases, membrane-type as well as other non-classified MMPs [4]. Each of these groups has its subunits that perform unique functions [5]. Chemokines, cytokines, as well as growth factors, cell-to-to-cell adhesion molecules, and binding proteins, can be mentioned as other potential targets for MMP substrates [6]. The classification of MMPs is indicated in Table 1 shown [7-11]. Matrix metalloproteinase (MMPs) activity might be regulated at three transcription levels, production of enzymes like zymogens, which require activation, as well as co-expression of tissue inhibitors of metalloproteinases (TIMPs) [12,13]. MMPs transcription is perfectly controlled, and their expression level of them is low. TIMPs are endogenous suppressors of metalloproteinases that can inhibit the MMM's catalytic activity, therefore maintaining ECM homeostasis [14]. MMPs are produced in their inactive zymogenic forms (proenzymes or pro-MMPs), which are subsequently proteolytically activated by removing propeptides by other proteases [15]. The majority of MMPs are activated in the extracellular space via plasma, tissues, and microbial proteases. The rest of the activated MMPs like MT-MMPs, MMP-11, 23, and 28 possess a furin-dependent cleavage motif RXK/RR in the propeptide sequence, which are intracellularly activated via furin-like proteases of Golgi [16]. Any disruption in the regulation of MMPs modulatory mechanisms may associate with the progression of the disease in pathological conditions [12].

Table 1: Classification of the main members of the MMP family by chromosomal location and the group of substrates

MMP number	MMP subclass/ Family/Group	MMP name	Substrates	Chromosome
MMP-1	Collagenases	Interstitial collagenase	Collagens (I,II,III,VIII a X); gelatin; aggrecan; L-selectin; IL-1β proteoglycans, entactin; ovostatin; MMP-2; MMP-9	11q22-q23
MMP-2	Gelatinases	Gelatinase A	Collagens (I,IV,V,VII,X,XI a XIV); gelatin; elastin; fibronectin; aggrecan; MBP; osteonectin; laminin-1; MMP-1; MMP-9; MMP-13	16q13
MMP-3	Stromelysins	Stromelysin 1	Collagens (III,IV.V, a IX); gelatin; aggrecan; perlecan; decorin; laminin; elastin; casein; osteonectin; ovostatin; antactin; plasminogen; MBP; IL-1β; MMP-2/TIMP-2; MMP-7; MMP8; MMP-9; MMP-13	11q23
MMP-7	Matrilysins	Matrilysins	Collagens (IV a X); gelatin; aggrecan; decorin; fibronectin; laminin; entactin; elastin; casein; transferrin; plasminogen; MBP; β4-integrin; MMP-1; MMP-2; MMP-9; MMP-9/TIMP-1	11q21-q22
MMP-8	Collagenases	Neutrophil collagenase	Collagens (I,II,III,V,VII,VIII a X); gelatin; aggrecan; fibronectin	11q21-q22
MMP-9	Gelatinases	Gelatinase B	Collagens (IV,V,VII,X a XIV); gelatin; entactin; aggrecan; elastin; fibronectin; osteonectin; plasminogen; MBP; IL-1β	20q11.2-q13.1
MMP-10	Stromelysins	Stromelysin 2	Collagens (III-V); gelatin; casein; aggrecan; elastin; MMP-1; MMP-8	11q22.3-q23
MMP-11	Stromelysins	Stromelysin 3	Unknown (casein)	22q11.2
MMP-12	Elastase	Metalloelastase	Collagen IV; gelatin; elastin; casein; fibronectin; vitronectin; laminin; entactin; MBP; fibrinogen; fibrin; plasminogen	11q22.2-q22.3
MMP-13	Collagenases	Collagenase-3	Collagens (I,II,III,IV,IX,X,a XIV); gelatin; plasminogen; aggrecan; perlecan; fibronectin; osteonectin; MMP-9	11q22.3
MMP-14	Membrane-MMP	MT1-MMP	Collagens (I-III); gelatin; casein; fibronectin; laminin; vitronectin; entactin; proteoglycans; MMP-2; MMP-13	14q11-q12
MMP-15	Membrane-MMP	MT2-MMP	Fibronectin; entactin; laminin; perlecan; MMP-2	16q12.2-q21
MMP-16	Membrane-MMP	MT3-MMP	Collagen III; gelatin; casein; fibronectin; MMP-2	8q21
MMP-17	Membrane-MMP	MT4-MMP	Gelatin	12q24
MMP-18	Collagenases	Collagenase-4	Unknown	Unknown
MMP-19	Other	RASI-1	Gelatin; tenascin; fibronectin; collagen IV; laminin; entactin; fibrin/fibrinogen; aggrecan	12q14
MMP-20	Other	Enamelysin	Amelogrenein; aggrecan; COMP	11q22
MMP-23	Other	Unnamed	Amelogenin	11q22
MMP-24	Membrane-MMP	MT5-MMP	Pro-MMP 2	20q11.2
MMP-25	Membrane-MMP	MT6-MMP	Pro-gelatinase A; fibrin; fibronectin; collagen IV; gelatin	16p/3.3
MMP-26	Matrilysins	Endometase, matrilysin-2	Gelatin Iα; P1; fibrinogen; fibronectin; vitronectin; β-casein	Unknown

MMPs AND TUMOR PROGRESSION

Cancer is the second factor of death globally, which is estimated to account for 9.6 million deaths in 2018 [17]. Recent two decades of biomedical research have led to large amounts of information about the molecular events which occur during carcinogenesis as well as signaling pathways involved in the progression of cancer. Complex molecular mechanisms play different roles in the tumor cells and the tumor environment associated with this process [18]. Several interactions of tumor cells with the involved environment of the tumor are crucial for the pathological changes observed during the transformation of cells and carcinogenesis in the extracellular matrix (ECM), as well as cytokines, growth factors associated with ECM, along with neighboring cells (neutrophils, endothelial cells, mast cells, macrophages, fat cells, and pericytes) [19-21]. Different steps of cancer consisting of migration, attack, metastasis, and angiogenesis are in interaction with the neighboring microenvironment [22]. MMPs are the main molecules in these processes, and since they break down numerous cell adhesion molecules, indicating their roles in the regulation of cell-to-cell, and cell-ECM interactions [23,24]. Previous researchers have identified that MMPs play an essential role in all phases of tumor maintenance and growth, including invasiveness, migration of tumor cells, evasion from apoptosis as well as immune surveillance, angiogenesis, and metastasis, so that all these major stages may be modulated by MMPs [25].

Interferon, interleukins, growth, factors, and extracellular MMP inducers secreted from tumor cells in a paracrine, manner stimulating adjacent host cells to generate the required MMPs. MMPs produced by normal cells can be bound and used on the surface of tumor cells [26]. MMPs gene expression and its activity increase in many types of cancers in humans. And this increased expression causes an increase in tumor size, invasion, and decreased survival [27]. Thus, MMPs are used as a novel and capable therapeutic target in different types and cancer phases [28]. MMPs use their proteolytic function to remove physical barriers, developing angiogenesis and tumor metastasis [29]. Tumor development and angiogenesis depend on the facilitated accessibility of signaling molecules. For example, cytokines and growth factors by MMPs enhance by making them available for tumor cells and their microenvironment [18]. This process is performed by releasing these factors from the ECM (VEGF, IGF, and bFGF) or via secreting them from the surface of the cell (HB-EGF, EGF, TGF-a) [4]. The release of endogenous angiogenesis suppressers can regulate angiogenesis perfectly, for instance, angiogenesis inhibitors like tumstatin, endostatin, angiostatin, and endorepellin [30]. Disruptions in the regulation of cell-cell and cell-ECM interactions by MMPs during the processing of E-cadherin and integrins, respectively, affect both cell phenotype (EMT) as well as increasing cell migration [31,32]. Almost all members of the MMP family have been reported to be dysregulated in human tumors, although MMPs such as MMP-1, -2, -7, -9, -13, and 14 are more important [33]. We have demonstrated the most noticeable MMPs, which are related to the phases of tumor growth, biological effects, and their consequences in Table 2.

Table 2: Key MMPs in relation to the stages of cancer progression, biological effect, and consequences

Function	MMP	Biological effect	Consequence	Reference
Cancer cell invasion	MT1-MMP, MMP-2 and MMP-9	Proteolytic	Breakdown physical barriers	[144]
Cancer cell proliferation	MMP-1, -2, -3, -7, -9, -11, -19	Cleavage of IGF binding proteins, Shedding of membrane, anchored ligands of EGFR, including HB-EGF, TGF-a and amphiregulin, Activation of TGF-β, Shedding of HB-EGF	Proliferation	[145-147] [148] [149] [150]
Cancer cell apoptosis	MMP-7 Several MMPs	Cleaving the Fas ligand Indirect activation of the serine/serine/threonine Akt ⁄ protein kinase B through the signaling cascades of EGFR and IGFR	Anti-apoptotic	[151] [147, 152]
Tumor angiogenesis	MMP-2, -9 MMP-3, -10, -11 MMP-1, -8, -13	Degradation of COL-IV, perlecan; release of VEGF and bFGF, respectively Degradation of COL-IV, COL-XVIII, perlecan; generation of tumstatin, endostatin, angiostatin and endorepellin, respectively	Upregulation of angiogenesis Downregulation of angiogenesis	[153, 154] [4, 155]
Cell adhesion, migration, and EMT	MMP-2 MT1-MMP MMPs MMP-2, -3, -9, -13, -14 MMP-1 and -7 MMP-28	Degradation of COL-IV; generation of cryptic peptides Degradation of laminin-5; generation of cryptic peptides Integrins as substrates Overexpression this MMPs associated with EMT, a highly conserved and fundamental process of morphological transition By cleavage E-cadherincontribute to morphological transition Proteolytic activation of TGF-β	Promote migration Induction of EMT; cell migration Powerful inducer of EMT, leading to cell migration	[156, 157] [158] [159] [160] [161]
Immune surveillance	MMP-9 MMP-9, -2, -14 MMP-7, -11, -1, -8, -3 MMP-7, -8	Cleavage of IL-2R alpha Release active TGF- β Release of a1-proteinase inhibitor Cleave several members of the CC (β-chemokine) and CXC (α-chemokine) chemokine subfamilies or to regulate their mobilization	Repress T-lymphocyte proliferation Abolish T-lymphocyte reaction against cancer cells Decrease cancer cell sensitivity to NK cells Affecting leukocyte infiltration and migration	[162] [163] [164] [165, 166]

ONCOVIRUSES

Approximately 20% of all human malignancies worldwide are associated with viruses [34]. Seven viruses have been implicated as oncogenic, including HPV, EBV, HCV, HBV, Kaposi's sarcoma-associated herpesvirus (KSHV), HTLV-1, and Merkel cell polyomavirus (MCV), which have been reported to be etiologically implicated in the maintenance and progression of human cancers [35]. However, viral oncogenesis processes are a complex process, with induction of chronic inflammation conditions, disruption of cellular DNA repair mechanisms, interrupting host genetic and epigenetic integrity, and homeostasis, viral infection may result in genome variation and cell cycle deregulation. Viral 'oncoproteins' are capable of modulating or deregulating cellular signaling pathways, making changes in the expression of genes and microRNAs in either transcription or post-transcription, and disrupting tumor suppressor factors and proteins, which regulate cell polarity, immune response, signal transduction, and cell apoptosis. Genetic and epigenetic modifications caused via oncoviruses may be resulting in the morphology and variation of cancer stem cells, which are essential for the primary initiation, development, migration, invasiveness, and chemotherapy resistance of tumors. These molecular events underlying the interactions between oncoviruses that use specific cellular genes and cellular signaling pathways are important issues to research efforts [36-38]. MMPs have several specific biological actions in every cancer phase, from the beginning to the extension of pertinent metastases. Accordingly, this review's focus is on characterizing the mechanism of modulation or deregulation of MMPs by oncoviruses.

INTERACTION BETWEEN ONCOVIRUSES AND MMPs

Epstein-Barr virus

Epstein-Barr virus (EBV) is a linear dsDNA virus that belongs to the human gamma-herpesvirus family, playing a role in different B-cells lymphomas, including Hodgkin's lymphoma, Burkitt's lymphoma, post-transplant lymphoproliferative disorders, as well as other tumors like T-cell non-Hodgkin lymphomas and nasopharyngeal carcinoma [39]. In tumors associated with EBV, the virus leads to a latent infection expressing only a subset of 12 latent viral transcripts, two early RNAs (EBERs), three latent membrane proteins (LMPs), six nuclear antigens (EBNAs), and BARF transcripts. Out of these genes, EBNA1, EBNA-2, EBNA-3A, EBNA-3C, EBNA-LP, and LMP1 enable the virus to control a number of cellular signaling pathways associated with oncogenesis [40,41]. EBV LMP1 increases MMP-9 expression by recruitment of Sp-1, AP-1, and NF-kappa B transcription factors on MMP-9 promoter that is related to invasiveness and metastasis in EBV-associated NPC [42]. Previous research demonstrated that C-terminal activation regions 1 and 2 (CTAR-1 and CTAR-2), two crucial signaling domains within the carboxy terminus of LMP1, might activate the MMP-9 promoter and stimulate MMP-9 activity [43]. TANG Jian showed EBV-induced MMP-9 upregulation correlates with lymph node metastasis and clinical stage in NPC tumors [44]. Lee demonstrated that upregulation of MMP1 and MMP3 expression in LMP1-positive NPC tumors led to the enhancement of invasiveness in NPC cells [45]. BZLF1 (also known as Zta) is one of the critical inducers of EBV lytic cycle alteration and has been reported to trigger metastasis in epithelial cells [46, 47]. In vitro studies demonstrated that Zta stimulates MMP3 and MMP9 expression in epithelial cells derived from NPC tumors. Zta can activate the MMP3 promoter by AP-1 elements, and its DNA-binding domain is necessary for the process of promoter binding and MMP3 stimulation. Zta-enhanced cell migration requires MMP3 but not MMP9. Zta-elevated cell migration needs MMP3, but not MMP9. Therefore, the expression of both MMP3 and MMP9 is important for the co-expression of the two MMPs (MMP3 and MMP9) induced by Zta, which simultaneously promotes cell invasiveness of epithelial cells differentiated from NPC tumor [48]. Moreover, Zta protein via binding AP-1 site of its promoter increases TIMP-1 expression in EBV-infected B-cells as well as EBV-immortalized lymphoblastoid cell lines (LCLs). Upregulation of TIMP-1 expression through Zta enhances the maintenance of EBV-infected B-cells and promotes the progression of EBV-associated cancer [49]. EBNA3C regulates the transcription of numerous viral as well as cellular genes important for the process of immortalization by EBV in primary B-lymphocytes [50]. Nm23-H1 is a well-known metastasis inhibitor, and its low expression is correlated with metastatic tumor capability in different types of human carcinoma [51]. In vitro research showed the interaction of EBNA3C with Nm23-H1 leads to the translocation of Nm23-H1 to the nucleus and inhibits the antimotility effect. However, studies have shown that this interaction also can increase transcriptional activity on a related promoter of the target gene [52]. Interaction between EBNA3C and Nm23-H1 upregulates the expression of MMP-9 by binding the transcription factors AP-1 and NF-kB on its promoter in B-cells that were isolated from Burkitt's lymphoma [53]. LMP2A promotes cell transformation, migration, and invasion by affecting host cellular signaling pathways, mainly by its N-terminus, intracellular domain, which consists of an immunoreceptor tyrosine-based activation motif (ITAM), a YEEA motif, and two PPPPY (PY) motif [54,55]. LMP2A promotes invasion of NPC cells by the PY motif via stimulation of extracellular signal-regulated kinase (ERK)-1/2 as well as the downstream transcription factor Fra-1, therefore leading to upregulation of MMP9 expression [56]. WW domain-containing oxidoreductase WOX1, also called WWOX or FOR, is a candidate tumor inhibitor encoded by the human fragile WWOX gene, related to several signaling pathways modulating embryonic development, metabolism, cell proliferation, and apoptosis [53]. The function of WOX1 in cancer suppression is commonly used by stimulating apoptosis and sequestering some oncoproteins [57,58]. According to a previous study, the interaction of the tyrosine residue 33 of WOX1 and the PY motif of LMP2A is needed for the LMP2A-induced ERK1/2-Fra-1-MMP9 pathway in NPC cells (Figure 1) [59]. Two SNPs (rs8113877T>G or rs17576A>G) of MMP-9 in ab_EBV positive individuals were associated with more possibility of progression to chronic lymphocytic leukemia in contrast to those individuals who were negative [60]. In summary, the upregulation of MMPs by EBV plays a significant role in EBV-triggered metastasis.

Human papillomavirus

Human papillomaviruses (HPVs), namely double-stranded DNA viruses, are recognized as one of the main agents that relate to the progression of numerous cancers such as head and neck, cervix, vagina, vulva, anal and penile carcinomas [61]. Continuing infection with high-risk human papillomavirus (HPV) types, especially HPV type 16 or 18, is essential for the development of a cancer precursor lesion and invasive cervical cancer, which is identified through deregulated and high-level expression of HPV early genes (E6 and E7) [62]. The high-risk HPV E6 and E7 oncoproteins result in transformation by a disruption in the activity of cellular tumor suppressor proteins p53 and RB, respectively, and several cellular proteins [63,64]. Induction of MT1-MMP expression in HaCaT cells, an immortalized human keratinocyte line, by the E7 protein of high-risk HPV types 16 and 8 contributes to cellular proliferation, angiogenesis, and, malignant progression, for the invasion of HPV-positive tumor cells [65]. In human keratinocytes and organotypic skin cultures, HPV8 E2 protein overexpresses the expression of MMP-9 by direct activation of its promoter, resulting in increased squamous fragility involved in facilitating viral escape [66]. A recent study demonstrated that HPV-16 E6/E7 oncoproteins cause upregulation of MT1-MMP, MMP-2, and MMP-9 to promote cervical cancer cells [67]. Previous studies reported that HPV 16 infection might lead to lung tumor cells through increasing in interleukin-17 (IL-17) expression. IL-17 along with its downstream signaling mediator, interleukin-8 (IL-8), play an efficient role in tumor angiogenesis and metastasis by modulation of various pro-angiogenic factors [68]. Induction of IL-8 by HPV upregulates the expression of MMP-2 and MMP-9 in lung adenocarcinoma that correlated with progressive mechanisms of growth, and metastatic and angiogenic characteristics [69]. HPV-16 E6/E7 overexpressed the expression of MT1-MMP and MMP-2, which are correlated with increased cell invasion in cervical cancer [70]. According to recent research (Haukioja), low salivary levels of MMP-8 are due to continued oral HPV infection, which appears like a failure of the anti-inflammatory defense of the oral mucosa to allow an incident oral HPV infection to become a chronic infection [71]. Common skin extract immunoblots and zymographic analysis revealed increased expression of MMP-9, MMP-13, and MT1-MMP in HPV8-positive mice rather than HPV8-negative mice, which are involved in the development of HPV8-induced cutaneous tumors (Figure 2) [72]. Singh et al. have shown that SNPs -1306CC (rs243865: C>T) in the promoter of the MMP2 gene, enhanced transcription and enzymatic activity of the MMP-2 gene is associated with the incidence possibility of cervical cancer. A significant relationship between the −1306CC genotype and HPV infection in increasing the risk of cervical cancer was observed [73].

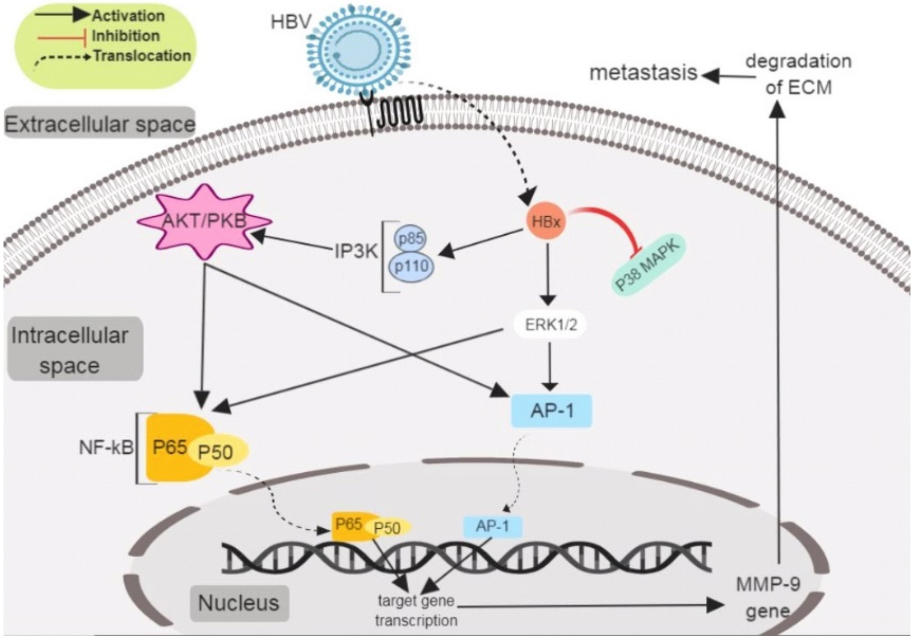
HBV

Chronic hepatitis B (CHB), an important agent responsible for liver cirrhosis and hepatocellular carcinoma, is among the primary health problems of the world [74,75]. HBV transactivator protein (HBx) enables the invasive capacity of the virus, which is mediated by increased the expression of membrane-type one matrix metalloproteinase (MT1-MMP) that subsequently activates matrix metalloproteinase-2. HBx is able to induce both MT1-MMP expression and cell invasion through dependence on cyclooxygenase-2 (COX-2) activity. Furthermore, HBx increases COX-2 expression through the activation of COX-2 gene promoter transcription in a nuclear factor of an activated T-cell-dependent (NF-AT–dependent) manner. These data indicated the capacity of HBx to augment tumor cell invasion by a mechanism consisting of MT1-MMP and COX-2 upregulation and led to new insights into HBx protein mechanism of action, its involvement in tumor metastasis and hepatocellular carcinoma resulting from intrahepatic metastasis to HBx protein expression following establishment of tumor [76]. HBx protein plays a crucial role in the progression of hepatocellular carcinoma (HCC). HBx is often the only HBV protein that would be detected in hepatic tumor cells, which enhances tumor cell invasion and metastasis. HBx, by inducing the PI-3K/AKT and ERK pathways except for the P38 MAPK pathway, leads to the activation of NF-kB and AP-1 transcription factors. HBx triggers the translocation of NF-kB and AP-1 into the nucleus, leading to increasing MMP-9 expression. Thus, HBx modulates the transcriptional function of MMP-9 that is essential to the incursion and metastasis of tumors through PI-3 K/AKT and

ERK pathways. These findings suggest that HBx could induce MMP-9 and, in turn, in the invasion and metastasis of cancer, by activating ERK and PI-3K signaling pathways (Figure 3) [77].

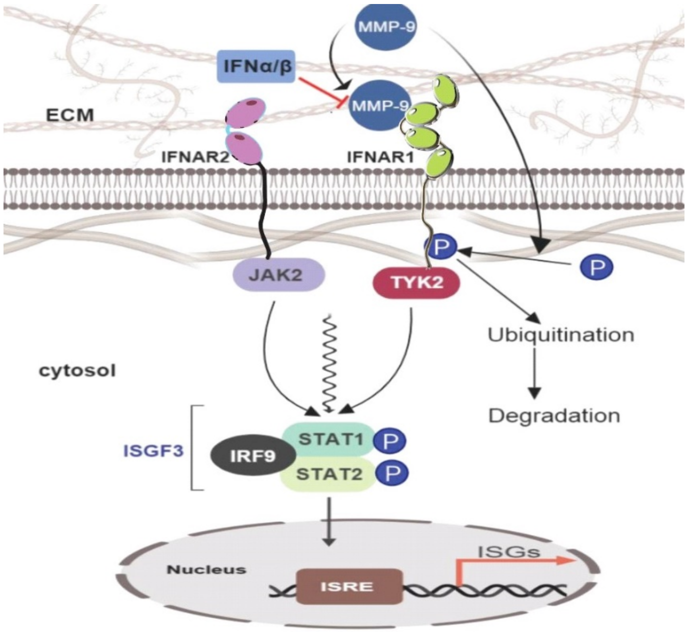
Figure 3: Molecular mechanism of HBX-activated MMP-9 expression. HBx induces PI-3K/AKT and ERK pathways but not the p38 MAPK pathway. This process leads to the stimulation of NF-kB and AP-1 transcription factors. Translocation of NF-kB and AP-1 activated by HBx into the nucleus leads to an increase of MMP-9 expression. Therefore, HBx via regulation of transcriptional activation of MMP-9, plays an important role in the invasion and metastasis of tumors via PI-3K/AKT and ERK pathways



Genes that were defined to be modulated in the presence of HBx include those genes involved in signal transduction, cell cycle, cytokine production, metabolism, apoptosis, cell adhesion, and oncogenesis. The functions of other less-defined genes also were affected. Transactivation by HBx upregulates the translation, transcription, and release of matrix metalloproteinase-3 (MMP-3), which manifests as a cell migratory phenotype. This effect of HBx was suppressed in the presence of an MMP-3-specific peptide inhibitor. HBx applies selective control of transcription in hepatoma cells as well as inducing cell migration via activation of MMP-3. Therefore, by upregulation of MMPs, HBx increases the invasion of tumor cells and the destruction of the extracellular matrix that is reported to increased cell migration [78]. The progression of tumors tightly depends on a permissive microenvironment that is highly correlated with the destiny of tumor cells. The normal structure of ECM is of high importance in the modulation of cell growth. For invasiveness, cancer cells must overwhelm the mechanical barriers caused by the ECM. It has been demonstrated which conformational changes in the ECM by MMPs have a noticeable role in the mobility and spread of tumor cells, resulting in invasion and metastasis. The activation of MMP induced by HBx signifies a role of HBx protein in the development of HCC metastasis. However, HBx is demonstrated to relieve transcriptional stimulation activity, it is not defined in what way HBx induces the expression of MT1-MMP [79,80]. HBV replication is assisted by MMP-9 through repression of IFN/JAK/STAT signaling as well as IFNAR1 function. Thus, these outcomes have discovered a novel role for MMP-9 in viral replication, revealing a new mechanism by which HBV escapes host immunity to maintain persistent infection. Indeed, there is a positive feedback loop between the injection of HBV and the production of MMP-9. Firstly, HBV activates MMP-9 production in PBMCs and macrophages. Subsequently, HBV replication would be facilitated by MMP-9 through repressing IFN/JAK/STAT signaling, interacting with IFNAR1 to prevent its binding to IFN-α and promoting the ubiquitination phosphorylation, degradation of IFNAR1 and ISRE, subcellular distribution, and interferon-stimulated response element. Thus, MMP-9 would benefit HBV by blocking innate immunity to launch or maintain chronic infection (Figure 4) [81].

In hepatitis B infection, apoptosis of liver cells that is induced by varying degrees of inflammation plays an essential role in the outcome of CHB [82]. The MMP-9 expression level is directly related to TNF-α and IL-6. Because IL-6 and TNF-α can regulate MMP-9 activity in a concentration- and time-dependent mode, overexpression of MMP-9 can degrade ECM to destroy the basement membrane and lead to disorganized and loose tissue structures, leading to further penetration of TNF-α and IL-6. These factors can interact with each other and create a vicious cycle, resulting in pathological changes in the liver. In conclusion, the MMP-9 level is increased remarkably in patients with varying degrees of CHB, it would be important in the pathological progress of the liver, and it has a close correlation with inflammation, which can provide a theoretical basis for clinical treatment [83].

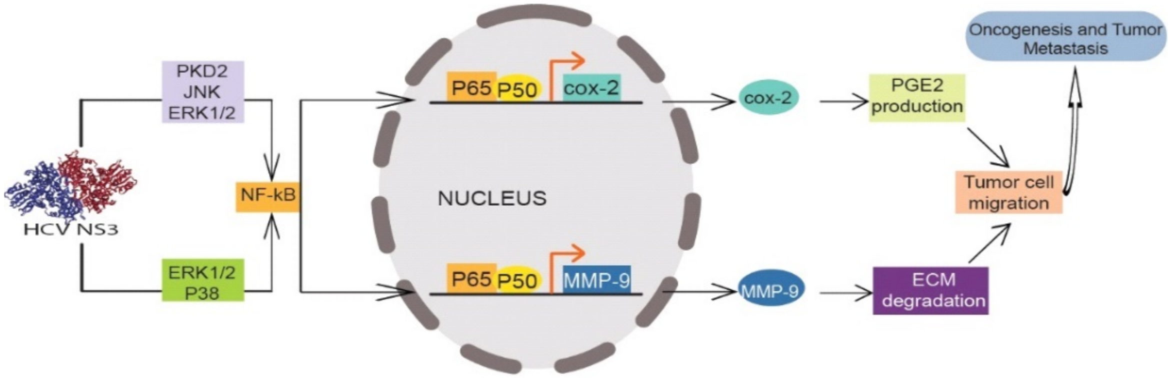
Figure 4: MMP-9 assists HBV replication by suppressing IFN/JAK/STAT signaling and IFNAR1. Indeed, HBV induces MMP-9 in infected patients and in HBV-stimulated leukocytes. Then, MMP-9 comforts HBV replication through repressing IFN/JAK/STAT signaling, interacting with IFNAR1 to block its binding to IFN-α, and promoting the phosphorylation, ubiquitination, subcellular distribution, and degradation of IFNAR1



HCV

Hepatic inflammation, cirrhosis, developing liver fibrosis, and hepatocellular carcinoma (HCC) are common problems in HCV patients [84,85]. In the liver, the main reason for fibrogenesis is pathological repletion of the extracellular matrix (ECM), which leads to an imbalance in the rate of enhanced matrix synthesis to reduce the degradation of connective tissue proteins that can be controlled by matrix metalloproteinases (MMPs). Recent studies showed that increasing levels of hepatic gelatinases, including MMP-9, and MMP-2, are related to the progression of HCC and the fibrotic index of chronic HCV patients [86,87]. The disparity between matrix metalloproteinases (MMPs) and tissue suppressors of matrix metalloproteinases (TIMPs) is remarked to be a significant index of degradation of the extracellular matrix. MMPs are members of gene families that can degrade collagen and play an essential role in the natural mechanism of tissue repair in pathological states, including liver fibrosis. Thus, an increase of the MMP-1/TIMP-1 ratio by IFN treatment can relieve liver fibrosis of chronic hepatitis C that demonstrates the anti-fibro genetic effect of IFN on the factors modulating hepatic fibrosis [88]. During chronic liver harm, activated hepatic stellate cells (HSC) turned backward into myofibroblast-like cells and proliferated. This stage is an important factor in the creation of fibrosis and subsequent cirrhosis [89]. HSCs are considered important sources of fibrillar as well as nonfibrillar collagens of the liver, matrix-degrading proteases (MMPs), and their specific blockers (TIMPs). Briefly, recent studies on patients with chronic hepatitis C reported important variations in hepatic TIMP and MMP expression. It is likely that TIMP expression was affected via the inflammatory conditions of the disease, which can reflect the effects of the disease. Promoted fibrosis enhances the expression of MMP-7 and MMP-2 and provides a condition for the destruction assessment of connective tissue [86]. The primary activity in the biosynthesis of different prostaglandins (PG) and thromboxanes catalyzes via cyclooxygenases [90,91]. There are two cyclooxygenases (COX) isoforms: COX-1 is basically expressed in several cell types and is the main factor in the homeostatic activity of PG, while COX-2 is triggered by different proinflammatory stimuli, including lipopolysaccharide (LPS) and cytokines [92-94]. COX-2 is involved in fibrogenesis, inflammation, and carcinogenesis [95-97]. Therefore, different researchers reported that increased COX-2 expression and PG production might be associated with liver dysfunction and tumorigenesis in various animal models [98-100], in addition to fibrosis and hepatocellular carcinoma (HCC) among humans [101,102]. HCV core and NS5A proteins, both alone and in association with the impact of endotoxin and proinflammatory cytokines, are capable of regulating the expression of COX-2 and MMP-9 genes through chronic HCV infection. Therefore, this mechanism may be considered evidence for this process that chronic HCV infection may result in liver fibrosis. Thus, it seems reasonable that much PGs generated in hepatocytes via the correlated effect of HCV proteins in addition to inflammatory factors may affect neighboring liver cells by autocrine and/or paracrine pathways, therefore participating in hepatocarcinogenesis [103]. The E2 envelope glycoprotein of the hepatitis C virus (HCV) is an important modulator of HCV interaction with cell surface receptors. E2 interacts with an extracellular loop of human CD81; it's a receptor expressed on various cell types such as hepatocytes and B-cells. CD81 on the cell surface is expressed in human hepatic stellate cells (HSC) at a high level, Matrix metalloproteinase-2 (MMP-2; gelatinase A), an important enzyme responsible for the degradation of the normal hepatic extracellular matrix, upregulates subsequently after binding E2 toCD81. Furthermore, E2/CD81 interaction in human HSC causes an increasing amount of MMP-2 via increasing the binding activity of activator protein-2/DNA via ERK/MAPK phosphorylation. Increased degradation of the hepatic extracellular matrix in HCV-concentrated regions may be associated with inflammatory as well as parenchymal damage [104]. HCV replication may be regulated by signal cascades, cellular factors, and viral proteins [105-108]. The HCV nonstructural protein 3 (NS3) has a serine protease required for the synthesis of viral protein and helicase activity needed for viral replication [109,110]. NS3 also is a major protein in modulating cell proliferation, indicating its role in carcinogenesis [111,112]. HCV NS3 protein facilitates tumor cell invasion in two ways. Firstly, NS3 induces several signaling pathways like protein kinase D2 (PKD2), JNK, and ERK1/2 to modulate the transcription factor NF-κB, and subsequently, it regulates the expression of COX-2 [113], and COX-2, in turn, activates MMP-9 expression. Secondly, NS3 induces the ERK1/2–p38 signal pathway to modulate the activity of NF-κB, which triggers the translocation of NF-κB to the nucleus and binding of NF-κB to MMP-9 promoter, which consequently upregulates MMP-9 expression. MMP-9 (an important enzyme in degrading the extracellular matrix), and COX-2 (the main enzyme in prostaglandin E2 production) exert key roles in tumor invasion and tumorigenesis. Therefore, NS3 enhanced tumor cell metastasis by MMP-9 and COX-2, leading to tumorigenesis (Figure 5) [114]. The MMP2, MMP9, and TNF-α levels have an effective increase in chronic HCV patients. However, no considerable correlation has been reported in the levels of MMPs and TNF-α between fibrotic and cirrhotic cases. In consequence, MMP2, MMP9, and TNF-α revealed high reproduction capacity in distinct patients afflicted with liver fibrosis (F1–F4) compared to the control group. In contrast, MMP9, MMP2, and TNF-α were not distinguishable factors for liver fibrosis in patients with chronic HCV. Therefore it is likely that they would be used as prognostic markers for liver fibrosis [115].

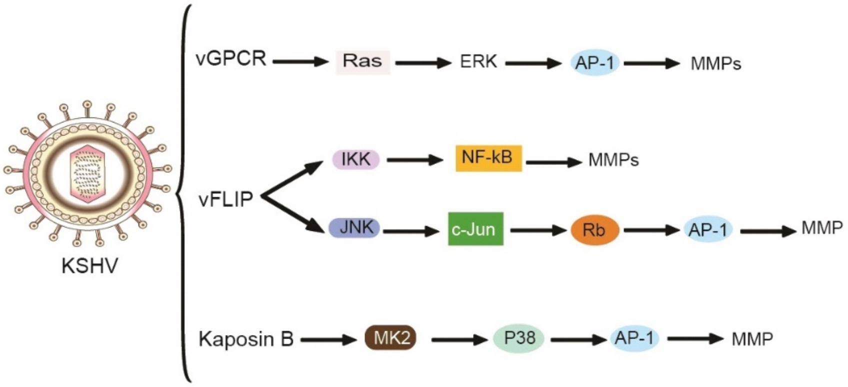
Figure 5: The mechanism of hepatoma cell invasion by HCV NS3 protein. First, NS3 activates multiple signaling components such as protein kinase D2 (PKD2), JNK, and ERK1/2 to regulate the activity of transcription factor NF-κB, which in turn regulates the expression of COX-2, and then COX-2 activates MMP-9 expression. Second, NS3 activates ERK1/2–p38 signaling pathway to regulate NF-κB activity, stimulates the translocation of NF-κB from the cytosol to the nucleus and the binding of NF-κB to the MMP-9 promoter, and thus activate MMP-9 expression.Thus, NS3 enhances tumor cell migration through COX-2 and MMP-9, resulting in oncogenesis or tumorigenesis



KSHV

Human herpesvirus-8 (HHV-8) or Kaposi sarcoma-associated herpesvirus (HHV-8 /KSHV) is a ds DNA virus with 165 kb in length. The HHV-8 life cycle consists of two states, lytic replication, and a latent phase. After primary infection, HHV-8 uses the cellular machinery of the host for replication and is subsequently observed in a latent phase as an episome. Like all herpesviruses, the B lymphocyte is the primary source of HHV-8 latency. The second sites for viral latency are endothelial cells, but these cells are the first infected cells in Kaposi sarcoma (KS). During latency, HHV-8 can regulate host cellular signaling pathways by different cellular mechanisms. Latent proteins, which include viral Cyclin a (v-Cyclin), LANA, kaposin, viral FLICE inhibitory protein (v-FLIP), and several miRNAs contribute to the pathogenesis of malignancies associated with HHV-8 [116]. HHV-8 has been identified in a Kaposi sarcoma lesion in an AIDS patient in 1994. This virus was reported to be associated with many B cell lymphoproliferative disorders (LPDs) such as posttransplant and germinotropic LPDs, multicentric Castleman disease (MCD), as well as primary effusion lymphoma (PEL) [117]. MMPs possibly associate with the mechanism of invasive KS growth and can be a proper target for effective therapeutic measures [118]. Developing KS lesional cells express gelatinases (MMP-2, MMP-9), stromelysin-1 (MMP-3), matrilysin (MMP-7), and collagenase (MMP-1, MMP-13) [119]. Cheng F. et al. demonstrated KSHV induces endothelial-to-mesenchymal transition (EMT). EMT was triggered by the viral proteins vGPCR and vFLIP via activation of the Notch pathway, which leads to a gain of membrane-type-1 matrix metalloproteinase (MT1-MMP) (Figure 6) [120]. The transcription factor PROX1 expression was recently investigated in KS. PROX1 binds the MMP14 promoter to repress its transcription. PROX1 negatively regulates MMP14 in normal tissues. Silvia Gramolelli et al. revealed that infection of lymphatic endothelial cells (LECs) with KSHV decreases PROX1 expression [121].

Figure 6: Schematic model of deregulation of MMPs by KSHV virus



Human T-cell lymphotropic virus type I (HTLV-I)

HTLV1 is a member of the retroviridae family, which is an etiologic factor of Adult T-cell Leukemia (ATL).ATL is a malignancy responsible for the extremely aggressive proliferation of CD4+ cells with no known cure [122]. ATL commonly originates from an infection that is acquired in early life [123]. Also, besides ATL, other manifestations of infiltrated T-cells, matrix metalloproteinases (MMPs), and cytokines of viral infection are Sjogren syndrome with an inflammatory appearance and HAM/TSP associated with neurological symptoms and incomplete paralysis of limbs [124-126]. The 3’ end of the genome (pX region) encodes some specific genes, including Rex, Tax, p12, p13, p30, and HTLV-1 bZIP factor (HBZ) [127,128]. HTLV-1 encodes two important genes, basic leucine zipper factor (HBZ), and tax, that are recognized to exert key roles in the infectivity of HTLV-1, survival, and growth of leukemic cells. Unlike HTLV-1 tax, HBZ escapes the antiviral response and is not detectable via the immune system. HTLV-1 provirus pX region encodes HBZ protein and in contrast to Tax, expressed in 100% of ATLL cells [123,129,130]. Although the proliferation of T cells is increased by HBZ, its function is interestingly antagonist to many tumorigenic activities of tax, such as activation of classical signaling pathways such as NFAT, AP-1, CREB, and NF-κB. Tax Repression through HBZ provides a condition for HTLV-1 to develop ATL by evading the immune system [123,131]. Tax may interact with cellular factors including AP-1, CBP/p300, CREB/ATF, and NF-κB. Both HTLV-1-replication and T-cell proliferation are generally enhanced by activating of IκB kinase (IKK)-NF-κB that is stimulated by viral Tax oncoproteins. Viral transactivator Tax is a presumed E3 ubiquitin ligase that is unitedly related with UbcH7, UhcH5c, and UbcH2 and is responsible for direct activation of IKK via binding to the NEMO subunit [132,133]. Bazarbachi et al. proved the interaction of HTLV-I-transformed cells in relation to endothelial cells triggers the gelatinase activity of MMP-9 and MMP-2 in endothelial cells and decreases the tissue blocker of MMP. In a study by Szymocha et al. on infected astrocytes (T cells) with HTLV-1, contact with T cells is the factor that the astrocyte obtains a typical phenotype of gliosis and causes the release of proinflammatory cytokines (i.e. IL-1 α, IL-6, TNF-α) and matrix metalloproteinases (MMP-3, MMP-9). The high expression of MMPs and their endogenous suppressors (TIMP-3 and TIMP-1) cause MMP/TIMP imbalance. It changes the extracellular matrix [134]. Giraudon et al. showed cytokines secreted by infected glial cells with HTLV-1 are responsible for increasing the expression of TIMP-3, and MMP-3, MMP-9, while MMP-2, TIMP-1, and TIMP-2 remained stable (Figure 7) [135].

MATRIX METALLOPROTEINASE INHIBITORS

Nowadays, MMPS targeting suppression of the activity of MMPs in the extracellular matrix as a novel anticancer strategy could be reconsidered. TIMPs, which are natural inhibitors of MMPs, at first, were the compounds to be developed for medical research. Hypothetically, TIMPs with potent inhibitory activity specifically can suppress the function of some MMPs which could lead to a useful therapeutic effect. However, their clinical application is still hampered by the absence of an efficient gene delivery style that has restricted the clinical use of this method [136]. Nevertheless, the progress of several types of natural synthetic suppressors of MMPs has been completely adopted and broadly investigated in clinical trials and researched in various cancers during the past decade (Table 3). Generally, synthetic suppressors of MMPs divide into three distinct pharmacologic groups including collagen non-peptidomimetics and peptidomimetics, tetracycline derivatives, and bisphosphonates [137].

THE RELATION BETWEEN INHIBITING OF MAJOR SIGNALING PATHWAYS BY MMP INHIBITORS AND ONCOVIRUSES

As previously mentioned, in HBV infection, HBx controls the transcription induction of MMP-9 which plays a key role in migration as well as metastasis of the tumor via PI-3 K/AKT and ERK pathways. Therefore, these data show that HBx plays a major role in inducing MMP-9 and, in turn, in the invasion and metastasis of cancer via activating ERK and PI-3K signaling pathways [77]. On the other hand, all the findings of one study already implied that 3-azidoWA suppresses 3-azidoWA-mediated MMP-2 expression through the attenuation of internal phospho-ERK as well as phospho-Akt expression in a dose-dependent condition that may have a significant role in the prevention of mouse angiogenesis as a natural inhibitor [138].

Table 3: An overview of the mechanisms deregulation MMPs by oncoviruses

Virus	Viral Factor	Number MMP	Mechanism/Effect	References
EBV	LMP1	MMP-9	Enhanced MMP-9 expression through induction of the MMP9 promoter by recruitment transcription factors AP-1, Sp-1, and NF-kappa B on MMP-9 promoter	[42]
	LMP1	MMP-1, MMP3	Upregulated MMP-1 and MMP-3 expression in NPC tumors	[45]
		MMP-9	Upregulated MMP-9 expression correlation with lymph nodes metastasis and clinical stage	[44]
	Zta	MMP-9, MMP-3	Overexpressed MMP-9 and MMP-3 expression in epithelial cells derived from NPC tumor	[48]
	EBNA3C	MMP-9	The interaction between EBNA3C and Nm23-H1 upregulated expression of MMP-9	[53]
	LMP2A	MMP-9	Upregulated MMP-9 expression by activation of extracellular signal-regulated kinase (ERK)-1/2 and a downstream transcription factor Fra-1	[56]
	Zta		Zta protein also up-regulated TIMP-1 gene expression in EBV-infected B cells and EBV-immortalized LCLs	[49]
HPV	E7	MT-1 MMP	E7 protein of the high-risk HPV types 16 and 8 lead to the induction of MT-1 MMP in in HaCaT cells	[65]
	E2	MMP-9	Increases the expression of MMP-9 in human keratinocytes and organotypic skin cultures	[66]
	E6/E7	MT1-MMP, MMP-2 and MMP-9	Upregulated expression of MT1-MMP, MMP-2 and MMP-9 in cervical cancer	[67]
		MMP-2, MMP-9	Up-Regulates MMP-2 and MMP-9 Expression and Activity by Inducing Interleukin-8 in Lung Adenocarcinomas	[69]
		MMP-8	Persistent oral HPV infection was associated with a low salivary MMP-8 concentration	[71]
		MMP-2, MMP-9, MMP-13 and MT1-MMP	Increased expression of MMP-9, MMP-13 and MT1-MMP in HPV8-positive mice than HPV8-negative animals	[72]
		MMP-2	A significant relationship was observed between the −1306C>T functional polymorphism in MMP-2 gene and HPV infection in increasing the cervical cancer risk	[73]
HBV	HBX	MT1-MMP, MMP-2	Up-regulated MT1-MMP expression by cyclooxygenase-2 (COX-2) activity and activates MMP-2	[76]
	HBX	MMP-9	Increased expression and regulate the transcriptional activaton of MMP-9 by activation of ERK and PI-3K signal pathways	[77]
	HBX	MMP-3	Up-regulated thetranscription,translationandsecretionofMMP-3	[78]
HCV	CORE AND NS5A	MMP-9	Up-regulated expression of MMP-9 with the synergistic effect of endotoxin and proinflammatory cytokines during chronic HCV infection	[103]
	E2	MMP-2	Up-regulation of MMP-2 by interaction between E2 and CD81and E2/CD81 interaction induced the up-regulation of MMP-2 by increasing activator protein-2/DNA binding activity via ERK/MAPK phosphorylation	[104]
	NS3	MMP-9	Activates MMP-9 expression by activates PKD2, JNK, and ERK1/2 to regulate NF-κB which regulates COX-2 expression , finally cox-2 activates mmp-9 expression	[114]
			Activates ERK1/2–p38 signal pathway to regulate NF-κB activity, stimulates the translocation of NF-κB from cytosol to the nucleus and the binding of NF-κB to the MMP-9 promoter	
KSHV	vGPCR and vFLIP	MT1-MMP	Increases of MT-MMP by induced EMT through activation of Notch pathway, leading to gain of MT1-MMP	[120]
		MMP-14	KSHV reduced prox-1 expression(Prox-1 binds to MMP14 promoter and represses its transcription),therefore prevents the repression of MMP-14 by prox-1 and induces mmp-14 expression	[121]
HTLV-1	TAX	MMP-2 MMP-9	Induces the gelatinase activity of MMP-9 and MMP-2 in endothelial cells and downregulates the tissue inhibitor of MMP	[134]
		MMP-9 MMP-3	Increases expression of MMP-9 and MMP-3 bysecreted proinflammatory cytokines (IL-1alpha, IL-6, TNF-alpha) by infected glial cells with HTLV-1	[134, 135]

Moreover, the results of a study by LU et al. provide molecules for the molecular signaling basis of the effects of newly synthesized quinazolinone MJ-29 on the inhibition of metastasis and invasion that could be beneficial as a therapeutic strategy to treat human oral cancer [139]. Accordingly, it can be concluded that 3-azidoWA and MJ-29 as natural MMP-9 inhibitors may have a more effective inhibitory ability on HBV, and HCV-related cancers by attenuating the internal phospho-ERK and phospho-Akt protein expression, which led to the repression of ERK and PI-3K signal pathways.

Other natural compounds such as curcumol via activation of JNK1/2, Akt, and nuclear translocation of NF-κB p65 [140], as well as magnolol through the inhibition of TNF-α by suppressing NF-κB binding activity [141], both caused the reduction of MMP-9 expression in MDA-MB-231 cells, breast cancer cell metastasis, and human urinary bladder cancer 5637 cells, respectively. Meanwhile, there is a possibility that these natural inhibitors can also modulate MMP-9 protein expression through multiple signaling pathways such as JNK, Akt, and TNF-α in HCV-related cancers. Antcin-H, a pure compound that is isolated from A.cinnamomea, can downregulate MMPs through inhibition of the FAK-ERK-C/EBP-/β/c-Fos-MMP-7 pathway, especially MMP-7 expression in renal cancer cell [142] (Table 4).

Table 4: Natural and synthetic inhibitors of MMPs in inhibiting targets of major signaling pathways in various types of cancer

Inhibitor	Class	Selectivity	Type of cancer studied	Inhibiting targets of major signaling pathways	Reference
Batimastat	Peptidomimetic	Broad spectrum	malignant ascites and malignant pleural effusion		[33]
Marimastat	Peptidomimetic	Broad spectrum	Breast cancer, small cell lung cancer, on-small cell lung cancer		[33]
BB-2516	Peptidomimetic	Broad spectrum	Head and neck squamous cell carcinoma (HNSCC)	through interference with autocrine loops in EGFR/c-erbB signaling pathways	[143]
BAY 12-9566	Nonpeptidomimetic inhibitor	MMP-2, MMP -3	advanced ovarian cancer, Breast cancer		[167]
AG3340	Nonpeptidomimetic inhibitor	MMP-2, MMP -3	non-small cell lung cancer		[168]
BMS-275291	Nonpeptidomimetic inhibitor	MMP-2, MMP -9	Non-small-cell lung cancer, prostate cancer, colorectal cancer, Breast cancer		[169, 170]
CGS 27023A	Small molecule	Broad spectrum	Advanced solid cancer		[33]
Col-3 (metastat)	Chemically modified tetracycline	MMP-2, MMP -9	Soft-tissue sarcoma, AIDS-related Kaposi's sarcoma, high-grade gliomas		[171, 172]
Prinomastat	Small molecule	Broad spectrum	Non-small cell lung cancer, , prostate cancer		[136]
Tanomastat	Small molecule	MMP-2, MMP-3, MMP-9	Ovarian cancer, adenocarcinoma of the pancreas, non-small cell lung cancer		[136]
Doxycycline	Tetracycline derivative	Broad spectrum	polycystic ovarian cancer		[136]
SB-3CT	Small molecule	MMP-2, MMP-9	T-cell lymphoma and prostate cancer models		[173]
ND-322	Small molecule	MMP-2/MT1-MMP	melanoma		[174]
curcumol	Major active components in the essential oil of RhizomaCurcumae	MMP-9	Breast cancer cell metastasis	via JNK1/2 and Akt(Ser473)-dependent NFκB signaling pathways	[140]
3 -azidoWA	derivative of Withaferin A	MMP-2	human cervical HeLa and prostate PC-3 cells	concomitant marked reduction in pAkt and pERK signaling by modulating extracellular par-4	[138]
MJ-29	2-phenyl6-pyrrolidinyl-4-quinazolinone derivatives	MMP-2/9	Oral squamous cell carcinoma	Down-regulation of MAPK and AKT Signaling	[139]
antcin-H	pure compound isolated from A. cinnamomea	MMP-7	Renal Cancer Cell	Partly through Inactivation of FAK-ERK-C/EBP-/β/c-Fos-MMP-7 Pathways	[142]
magnolol	the main constituent of Magnoliaceae	MMP-9	human urinary bladder cancer 5637 cells	Inhibition TNF-α-induced MMP-9 expression by suppressing NF-κB binding activities	[141]

The presence of MMP-inhibitory effects in virus-related cancers is still unknown. It has been determined that BB-2516, among all synthetic inhibitors, decreases the protein expression of a broad spectrum of MMPs by interfering with autocrine loops of EGFR/c-erbB signaling pathway in head and neck squamous cell carcinoma (HNSCC) [143]. However, more studies are necessary to understand the connections between MMP inhibitors and these signaling pathways in oncovirus-related cancers, making it especially important to examine how the relationships are.

CONCLUSIONS

In summary, matrix metalloproteinases as cellular proteases play the main role in biological processes as well as pathological conditions, including tissue repair, wound healing, developmental morphogenesis, inflammatory diseases, and tumor progression. Oncoviruses, in many cases, promote tumor progression through multiple mechanisms that affect the expression of these cell proteases. As oncoviruses upregulate the expression of MMPs genes through direct (via DNA binding) as well as indirect interactions (via activating PI-3K/AKT, ERK/MAPK, IFN/JAK/STAT, JNK, NF-κB signaling pathways or immune response), causing escape from the immune system and play a key role in cell proliferation, migration, angiogenesis, EMT, invasion, metastatic features, and subsequent tumor progression. Today, several compounds have been studied as matrix metalloproteinase inhibitors. Various studies have shown that these inhibitors activate the immune system and suppress tumor progression by inhibiting signaling pathways activated by viruses. With these interpretations, these cell proteases may be used as biomarkers to detect different stages of the development of oncovirus-related tumors, soon followed by inhibitors of these proteases in the treatment of viral tumors.

Conflict of interest

The authors report no conflicts of interest.

Acknowledgments

Authors wish to thank all staff of Applied Microbiology Research Center and Nanobiotechnology Research Center of Baqiyatallah University of Medical Science; Tehran; Iran, for their cooperation in implementing the experimental procedures and analysis of data.

Ethics approval and consent to participate

The study protocol was reviewed and approved by the ethics committee of the Baqiyatallah University of Medical Sciences (IR.BMSU.REC.1399.520).

Funding Statement

This study was fully sponsored by Baqiyatallah University of Medical Science; Tehran; Iran.

Abstract: *Background: Cardiovascular disease can be triggered and accelerated by hypertension and the underlying changes in the structure and function of arteries. The purpose of this review is to explore some vascular changes that occur in hypertension as a consequence of the imbalance between cell proliferation and cell death, processes that play an important role in stabilizing the thickness of the arterial wall during vascular remodeling. Methods: The authors conducted research through PubMed and Google Scholar databases using the following search formula: (hypertensive*) AND ((vascular modifications)) OR (vascular changes)) AND (cell death). Results: From 40 articles, only 17 publications were included in this study, taking into account four processes that can be preceded or followed by inflammation and depend on the interaction between local growth factors, vasoactive substances, and hemodynamic stimuli: Cell proliferation and growth; Cell migration; Cell death; Degradation or reorganization of extracellular matrix. Conclusions: To summarize, maladaptive vascular changes in hypertension can represent a major argument for prompt and maximal therapeutic intervention in patients with high cardiovascular risk. Moreover, they can represent an important step in discovering new markers of cardiovascular risk and in the development of new targeted therapies for different pathways of cellular signaling through which the reversibility of abnormal vascular changes could be obtained.*

Keywords: *cell death; inflammation; cellular metabolism alteration; vascular remodeling; hypertension; pathophysiology*

INTRODUCTION

Cardiovascular disease, one of the leading causes of death worldwide, can be triggered and accelerated by hypertension and the underlying changes in the structure and function of arteries. Knowing the pathophysiological mechanisms that are responsible for the maladaptive changes occurring at the vascular level in the context of hypertension, can represent a first step in the development of new targeted therapies for different pathways through which the reversibility of the abnormal vascular changes can be obtained.

Some studies have shown that hypertension linked to the imbalance between cell death and cell proliferation could explain vascular remodeling: accelerates endothelial apoptosis, promotes cell migration, and accelerates the proliferation of vascular smooth muscle cells [1] resulting in the thickening of the middle tunic of the arteries [1,2]. The role of cell death in blood pressure charge is still unknown [3]. The prevalence of hypertension increases with age and the proposed pathophysiological mechanisms are represented by hemodynamic changes, arterial stiffness (due to elastic lamina disruption and intimal hyperplasia), and neurohormonal and renal dysfunction [4]. In the elderly, vascular injuries can heal through the formation of vascular scars due to the increase in the proliferation of smooth muscle cells and the reduction of their apoptosis and decrease in sensitivity to apoptotic stimuli in fibroblasts and myofibroblasts, with secondary fibrosis [5,6].

In terms of the cell death process, some major pathways have been described (apoptosis, necrosis, and autophagy), depending on the injury and the type of cell [7]. Programmed cell death and necrotic cell death sometimes have mechanisms that can be overlapped [5]. The initiation of apoptosis is the result of death signaling pathways, intrinsic (mechanisms triggered by cellular stress through hypoxia, oxidative stress, and ADN damage) or extrinsic (mediated by transmembrane receptors of the TNF receptors family). In apoptosis, an essential process in maintaining tissue homeostasis, as a result of caspase cascade activation and imbalance between pro and antiapoptotic factors, the cell is broken for-ming membrane-bound vesicles and apoptotic bodies (after the shrinkage of the cell, fragmentation of nucleus and chromatin and plasma membrane blebbing [7]) responsible for clearance of dead cells and also for intercellular communication [8]. Necrosis is an accidental form of cell death but in certain instances is initiated or modulated under programmed control mechanisms. Unlike apoptosis, which requires energy consumption, necrosis is a process in which cells die without energy consumption; in the necrotic cell death process, as a result of the breaking of the cell membrane and the elimination of the cell content in the extra-cellular space, inflammation occurs. It has been described as a form of programmed necrosis (necroptosis), caspase-independent, with mitochondrial changes involvement [5]. Another type of cell death, autophagy, is the process through a staving or deprivation of growth factors cell generate energy and metabolites by digesting its organelles or macromolecules. There were also described multiple sub-types of cell death, depending on caspase involvement or the presence of some of the necrosis criteria: aponecrosis, paraptosis, anoikis, cornification, etc [5].

Recent studies examine how certain factors affect endothelial apoptosis in patients with hypertension and other comorbidities [1,4,9]. Endothelial cell apoptosis was found in patients with hypertension and peripheral arterial disease by studying endothelial cell cultures [9]. Vascular cell re-modeling, an active process, involves changes in at least 4 cellular processes: cell growth and cell migration, inflammation, cell death, and degradation or reorganization of the extracellular matrix. It is dependent on the interaction between local growth factors, vasoactive substances, and hemodynamic stimuli [10].

Although the in vitro studies [11] demonstrated a relationship between the level of some plasma membrane receptors involved in apoptosis induction (named death receptors) [12] and the phenomenon of apoptosis, the causal link between cell death and vascular changes was not proved yet [11].

Considering that the phenomenon of cell death and cardiovascular outcomes are linked through metabolic risk factors intervention and exogenous causes of cellular stress that lead to cell destruction via different pathways and demonstrating to what extent the alteration of cellular signaling, the alteration of the extracellular environment and the triggering of cell death mechanisms are responsible for the abnormal remodeling of the arterial wall in the hypertensive patients, the research could be directed to discover new markers of cardiovascular risk and new therapies that can be targeted in patients with cardiovascular risk factors. The benefit could be major, the measurement of death receptors levels related to cell death phenomena that can predict cardiovascular outcomes and death [11], in patients with high cardiovascular risk, became a major argument for prompt and maximal therapeutic intervention in this specific populational group.

The purpose of this review is to explore some vascular changes that occur in hypertension as a consequence of an imbalance between cell proliferation and cell death, processes that play an important role in stabilizing the thickness of the arterial wall during vascular remodeling.

MATERIALS AND METHODS

A comprehensive search through PubMed and Google Scholar using the following search formula: (hypertension*) AND ((vascular modifications)) OR (vascular changes)) AND (cell death) was performed. Only full-text freely available articles published in English between 2000 and 2021 were used. Articles that were most relevant to the subject of this review were included after thorough consideration. Inclusion criteria were published in English, publication within the mentioned period, and inclusion of hypertensive models or animal models, or cell cultures studies. From 40 articles, only 17 publications were included in this study. All the selected papers were reviewed by an independent reviewer to check that the interpretations were correct.

Hypertension has a great impact on the cardiovascular system; the thickness of the arterial wall during the remodeling process could be the result of cell death mechanisms triggered by factors potentially involved in the etiology of arterial hypertension. Considering that the connection between cell proliferation and cell death is responsible by a vascular re-modeling process in hypertension, we take into account for our study four processes that can be preceded or followed by inflammation and depend on the interaction between local growth factors, vasoactive substances, and hemodynamic stimuli:
- Cell proliferation and growth
- Cell migration
- Cell death
- Degradation or reorganization of extracellular matrix

RESULTS

The search strategy identified 40 articles of which 17 were deemed to be eligible for inclusion in this systematic review. Of these, 12 studies addressed markers of cell prolifera-tion/growth, 7 studies addressed cell migration, 12 studies addressed cell death processes/markers, 7 studies focused on the degradation of extracellular matrix, and 13 studies addressed inflammation markers (shown in Table 1).

In hypertension, the connection between cell proliferation and cell death could be critical in determining the thickness of the arterial wall during the remodeling process. There are 2 types of criteria for classifying cell remodeling:

- according to the size of the middle tunic: hypertrophic, eutrophic, and hypotrophic
- according to the size of the lumen: internal and external remodeling.

The consequences of cell remodeling are:

- high pulse pressure,
- stiffening of the arterial wall
- changes in the extracellular matrix.

All consequences of cell remodeling are determined by the release of growth factors and cytokines. The immune system, namely T lymphocytes, plays a key role in remodeling, more precisely based on a T-reg/T-effector imbalance.

Because of its ability to modify the vascular tone, vascular endothelium plays a significant role in hypertension. Endothelial dysfunction is caused by a reduction in nitric oxide (NO) availability, which causes endothelial dysfunction. The main cause of the decline in NO is the excessive production of reactive oxygen species (ROS)[13].

Blood pressure is affected by the phenomenon of cell death that can occur at different levels of the arterial wall, however, in hypertension the role of different types of vascular cell death is unclear. Researchers discovered that vascular smooth muscle cell growth is increased by cell death [1]. The cell death process is thought to play a key part in remodeling, but it is unclear whether it is the main process or a growth-related compensatory mechanism, being influenced by reactive oxygen species, NO, angiotensin type 2 (AT-II), and endothelins.

Due to vascular damage, elevated blood pressure values may alter the integrity of the endothelium and may also represent a risk factor for the onset and progression of vascular atherosclerosis changes leading to the destabilization of atheroma plaques [14]. Atherosclerosis favors the processes of inflammation and necrosis of the blood vessel and plaque can become unstable without proper treatment and cause even more complications.

DISCUSSION

In our study, we collected a lot of information about vascular modifications in hypertension. From the 17 selected articles, in 15 we found information about vascular remodeling (88.23%), in 14 articles we found arguments for the presence of the inflammatory phenomenon (82.35%), 13 articles (77.47%) argued for the presence of cell death and also 13 described cell proliferation, 7 articles (41.17%) described the phenomenon of cell migration, and 8 articles (47.05%) described reorganization of the extracellular matrix.

Starting from the information provided by the articles included in our study, our hypothesis related to the involvement of cell death at the vascular level in arterial hypertension seems to be valid. Maintaining a balance between the processes of cell proliferation, cell migration, cell death, and degradation of the extracellular matrix could ensure adequate vascular elasticity and delay the installation of specific hypertensive vascular changes. It seems that cells from all layers of the vascular wall are involved and can be affected by different types of death, the damage to each cell type leading to cellular metabolic changes and changes in the extracellular environment.

Vascular tone and vascular remodeling

The endothelial cells which form the tunica interna of the arterial wall, are essential for regulating hemostasis, vascular tone, and host defense [15]. Secretion, protection as a barrier, and local metabolism are the endothelium's three primary activities, each of which is altered by hypertension. The endothelial cells produce vasoactive substances such as nitric oxide (NO), carbon monoxide (CO), hydrogen sulfide (H2S)[15], prostacyclin (PGI2), endothelin 1 (ET-1), AT-II, prostaglandins. Normally, there is an equilibrium between these substances to maintain proper blood flow. In hypertension, at the vascular level is an increased production of vasoconstrictor factors (ET-1, AT-II, prostaglandins) which determine endothelium dysfunction (increased permeability, induce inflammation, and edema). It was discovered that the substances and structures that are released from a cell when it dies can affect the endothelial function in an autocrine, paracrine or endocrine model [16].

The endothelium is important for both short-term vascular tone modulation and long-term vascular remodeling. Nitric oxide is the most significant endothelium-derived vasodilator molecule which, under healthy conditions, is capable of inhibiting the primary fundamental pathways driving the formation of atherosclerosis and thereby improving vascular health. Reduced NO availability and endothelial dysfunction are caused by NO breakdown by reactive oxygen species (ROS) in physiological aging and many pathological diseases, including arterial hypertension.

Essential hypertension patients (HT) had a lower endothelial response to acetylcholine (Ach) than normotensive people (NT) in each age group, but it was proved that the vascular response to Ach in both HT and NT patients decreases as they become older [17]. In the pathogenesis of endothelial dysfunction and the cardiovascular consequences related to endothelial inflammation [18], apart from the effects of nitric oxide and carbon monoxide, the role of hydrogen sulfide has been also described. H2S formation was detected in smooth muscle cells, vascular endothelial cells, and cardiomyocytes and it was shown that H2S could protect endothelial cells against apoptosis by attenuating the overproduction of ROS and inhibiting mitochondrial apoptosis [15].

The vascular smooth muscle cells (VSMCs) that form tunica media are responsible for vasoconstriction, vasodilatation, and the process of remodeling [19]. The hyperplasia and hypertrophy of VSMCs are the processes that underlie vascular remodeling. The most frequent type of remodeling in hypertension is the inward type causing the narrowing of the arterial lumen. The outward type of remodeling occurs during anti-hypertensive treatment and is also caused by increased blood flow[16]. Some studies have revealed that a marked cell death influences and accelerates the proliferation of vascular smooth muscle cells, resulting in the thickening of the middle tunic of the arteries [2]. As a result of cell death through necrosis and the breakdown of plasma membrane integrity, the contents of necrotic cells are released, triggering a proinflammatory response [3].

Fibroblasts that form the tunica externa secrete chemokines, cytokines, and growth factors that contribute to normal vascular function and participate in the degradation of the extracellular matrix components. They play an important role in remodeling as a response to injury. However, fibroblasts suffer structural changes that are accompanied by proliferation and migration into the tunica media during hypertension [16].

Cell remodeling

Cell remodeling involves cell growth and cell migration, cell death, and degradation of the extracellular matrix and is dependent on multiple factors [10]. The media-to-lumen ratio (M/L), modifying the vessel wall width for increasing muscle mass, the reorganization of cellular and noncellular elements and the lumen dimensions are the most prominent manifestations of these adaptations [20]. As a result, remodeling can be classified based on the degree of change of the medium arterial tunic in hypertrophic, which is the most common, hypotrophic, or eutrophic remodeling, as well as the size of the lumen in internal or exterior remodeling [21]. With age, large arteries undergo outward hypertrophic remodeling and stiffening [4], and in hypertension, this process may be accelerated, resulting in higher pulse pressure [22-24]. The elastic laminae, on the other hand, develop multiplication and fragmentation in severe hypertension, with increased deposition of collagen and fetal fibronectin, leading to greater stiffness [23]. Small artery remodeling has typically been associated with increased media thickness in hypertension, but new studies have shown that there are two forms of remodeling, inward eutrophic and inward hypertrophic, depending on whether the media cross-sectional area is enlarged [23]. The discovery that inward eutrophic remodeling may be prominent in some kinds of hypertension has raised the prospect that countervailing mechanisms in hypertension, including apoptosis, may compensate for or modify growth [23,25]. The outer and lumen diameters are decreased, the media cross-sectional area is unchanged and the M/L is increased without stiffening in inward eutrophic remodeling [25]. Inward eutrophic remodeling reduces the outer diameter of the vessel through a mix of growth and apoptosis, with apoptosis concentrated to the periphery, whilst inward growth decreases lumen diameter, which may explain the preservation of media volume. It is uncertain whether apoptosis is a growth-related compensatory mechanism or a primary process[25]. Mechanical forces exerted on the arterial wall also play a significant role in remodeling. Changes in the extracellular matrix, the cellular release of growth factors and cytokines, and vascular sensitivity to circulating humoral factors are all caused by them. Force duration, load, and force properties all have an impact on all of these factors [1].

Low-grade inflammation

In hypertension and cardiovascular disease, low-grade inflammation plays a critical pathogenic function [26-28]. Innate and adaptive immune systems, specifically T cells, are implicated, according to a significant body of research. T-lymphocytes play a key role in the development of hyper-tension-related vascular remodeling. The balance between T-effector and Treg lymphocytes is a critical regulatory system that, when disrupted, favors blood pressure increase and the development of organ damage [21]. Treg lymphocytes have potent anti-inflammatory characteristics, ensuring vascular homeostasis and protecting the arterial wall against the onset of atherosclerosis [21,29]. In humans, the majority of data establishing essential hypertension as a chronic low-grade inflammatory state found a clear and independent link between c-reactive protein (CRP), tumor necrosis factor (TNF), Interleukin 1 beta (IL-1 beta)[30], Interleukin-6 (IL-6), and adhesion molecules and vascular alterations in essential hypertensive patients [21].

An important role in the process of vascular remodeling is played by the renin-angiotensin-aldosterone system (RAAS)[29,31] because of its role in VSMC migration and inflammation [24,32]. This system acts through 2 types of angiotensin II receptors AT1-R and AT2-R, but the AT1-R is thought to be the primary receptor that causes Ang II's proliferative and profibrotic actions [20,33]. The AT2-Rs are thought to cause opposite effects, preventing vascular deterioration. But there are times when AT2-R acts similarly to AT1-R (for example, in renovascular hypertension it causes tonic renal medullary vasoconstriction) [32,34]. Recent studies showed that there exists an AT1-R autoantibody (AT1-AA) which is an agonist of AT1-R. AT1-AA raises AT2-R expression and encourages cell migration through cytoskeletal remodeling [34]. The RAAS is implicated in physiological and pathological actions when it comes to vascular changes. It reduces ROS generation and modifies vascular tone via vasoconstriction and vasodilatation. During hypertension, this RAA system induces fibroblast proliferation, collagen deposition, and vascular hypertrophy [20].

Cell death

Apoptosis is a type of gene-controlled cell death that was first discovered in development as a mechanism for fine-tuning growth. The vascular system has a large number of apoptosis modulators. Reactive oxygen species, NO, angiotensin type 2 receptors, and the endothelin system are all possible candidates. Reactive oxygen species play a key role in the pathogenesis of hypertension and vascular cell apoptosis [35], with O_2^- inducing proliferation and H_2O_2 inducing apoptosis through a protein kinase C–dependent pathway, respectively. Angiotensin II is also a potential apoptotic trigger [25,31,36].

Recent studies examine how certain factors affect endothelial apoptosis in patients with hypertension and other comorbidities. Endothelial cell apoptosis was found in patients with hypertension and peripheral arterial disease (PAD) by studying endothelial cell cultures. They demonstrated that physical activity can lower this type of cell death[9]. PAD patients present increased cardiovascular stress, inflammation, and oxidative stress. Inflammation and oxidative stress speed up the progression of myopathy and increase the risk of apoptosis and sarcopenia. In older persons, exercise decreases oxidative stress and improves reactivity to oxidative processes [9].

Inflammation, VSMC apoptosis, and oxidative stress in patients with hypertension [1,18,19] can also play an important role in the pathology of abdominal aortic aneurysm AAA [37,38]. According to some studies [39] a member of the seric proteinase inhibitor superfamily, Human Kallistatin, acts as a protective factor by blocking the pathway that stimulates AAA generation [39], and even whey-protein supplementation has a beneficial effect, improving vascular function by inhibiting the serum angiotensin-converting enzyme [40].

Lesions that appear on the arterial wall and the dysfunction of endothelial cells determined by high blood pressure values are factors that contribute to atherosclerosis. In the injured artery intima, extra low-density lipoprotein (LDL) accumulated suffer processes of oxidation and can attract monocytes and macrophages, forming the foam cells. The local inflammatory reaction is severe [41] and it triggers a cascade of events [38,42]. Foam cell secretion, deposition, and apoptosis [43] are crucial steps in the occurrence of atheroma plaque [44]. In advanced stages, the macrophage function of phagocytosis is destabilized, the atheromatous plaque continues to grow and, in the end, it will become unstable, promoting local inflammation and necrosis without the proper treatment [41]. Studies have revealed that at the cellular level microRNA plays a role in the control of atherosclerosis [41,45], acting on the TGF-β signaling pathway, inducing proliferation, migration, and apoptosis of endothelial cells, VSMCs, and macrophages [37,43,46].

Sometimes, associated with long-term uncontrolled hypertension and left ventricular dysfunction (or other conditions such as left heart disease, thromboembolic pulmonary condition, lung disease, liver disease, hematologic disease, metabolic disease, connective tissue disease, human immunodeficiency virus infection, thyroid diseases, etc.), pulmonary hypertension may occur [47,48]. In this situation, through the lungs arteries that have a reduced lumen and thickened walls, blood will flow slowly. Pulmonary arterial hypertension (PAH) is defined by mean pulmonary arterial pressure (mPAP)>20 mmHg at rest assessed by right heart catheterization [47-49]. Histopathological changes at the pulmonary level are neointima formation in pulmonary arteries, wall thickness, and plexiform lesions formed by the proliferation of endothelial cells. There is an increased level of ROS that contributes to oxidative stress and vascular remodeling [50], similar to the changes found in the arteries of hypertensive patients. It has been discovered that there is a deficient activity of NO-synthase, the level of NO is low and so are the vasodilatory effects. The role of proapoptotic and antiapoptotic proteins has been incriminated in the initiation of the pathogenesis of PAH and the proliferation of apoptosis-resistant vascular cells [51,52]. Both reversible and irreversible PAH express the apoptotic markers (caspase-3 and p-53) [51,53], while irreversible PAH expresses BCL-2 only in severely wounded endothelial cells [51]. Apoptosis plays an important role in pulmonary hypertension among the proliferation of VCMCs and plexiform lesions [51,52].

In our study we highlighted some evidence in favor of the hypothesis that cell death is involved and has consequences on vascular changes in people with arterial hypertension; the vascular changes occurring in the hypertensive patient may be due to the alteration of the cellular metabolism, which may represent a triggering factor of cell death processes by activating abnormal cellular signaling pathways. However, there are insufficient data to show the cell death types involved and the types of cells in the vascular walls involved in the process of vascular remodeling, therefore we consider that further studies are necessary to elucidate these aspects

CONCLUSIONS

Cell death and cardiovascular outcomes seem to be linked through metabolic risk factors intervention and exogenous causes of cellular stress. Demonstrating that alteration of cellular signaling, the alteration of the extracellular environment, and abnormal cell death mechanisms are responsible for the abnormal remodeling of the arterial wall in hypertensive patients could direct future research toward the identification of new molecules as plasma membrane receptors involved in apoptosis and new therapies that can be targeted in patients with cardiovascular risk factors. Once the vascular impact of imbalances between cell proliferation and cell death will be demonstrated, its early detection could become an argument for maximum therapeutic intervention in this population group.

Abstract: *This article aims to highlight the burnout burden among neurologists and provide information on some of its causes and consequences. We report an original article that reviews our current understanding of burnout matter in the neurology field. The main search engine through which we performed extensive literature research was PubMed, Scopus, and Google Scholar. The following information was collected: triggers of burnout and factors that perpetuate it, major complaints, values, and goals that dictate how coaching with it. Physician burnout is an umbrella term characterized by symptoms determined by exposure to chronic workplace stressors. Simply put, it encompasses many dimensions: emotional exhaustion, feelings of cynism, detachment (depersonalization), and a sense of ineffectiveness at work (low personal accomplishment). Burnout is common among all medical specialties, but neurology ranks at the top of the list. Several identified factors continue to fuel this problem. Properly addressing them, rethinking practice, and implementing wise, modern strategies can make significant contributions to reducing it. Aside from the chronic harm to the physician, burnout puts at risk the healthcare community at many levels including patients, other professionals, finances, etc. This paper wants to emphasize that burnout in neurology should be regarded as a global crisis. Thus, some strategies are proposed.*

Keywords: *neurology, burnout, work-life, emotional exhaustion, stress, fatigue, depersonalization, second-victim phenomenon, complaints, functional neurology*

INTRODUCTION

Physician burnout is an umbrella term characterized by symptoms in response to prolonged exposure to chronic stressors related to the workplace. This topic attracted interest from researchers since it exhibits a concerning prevalence. In the field of medicine, we can consider burnout a pandemic that has a negative impact both on doctors and their patients, but most of the time this reaches far beyond that, to families and the overall healthcare system. All medical specialties are affected, but some of them carry a higher percentage of burnout. Over 40% of general physicians experienced at least one symptom of burnout, neurology being ranked the second specialty affected, with more than 60% of neurologists signaling symptoms [1,2]. Medscape 2022 report on Physician Burnout and Depression showed that 47% of neurology specialists are experiencing mental health challenges, which represents a substantial increase in its prevalence compared with the previous year's reports when it was 42% [3]. The purpose of this article is to highlight the burnout burden among neurologists and provide information on some of its causes and consequences.

BURNOUT AND NEUROLOGY

To date, many research studies have contributed to a comprehensive overview and understanding of the root causes that fuel physician burnout.

The prevalence of neurological disorders increased in the last two centuries and the increased burden that comes along can be attributed to explosive population growth, people reaching older ages, unhealthy lifestyles, and unawareness of the importance of prophylactic measures [4].

In opposition to this growth, the global shortage of neurologists led to inequalities in the availability of patient care with those already existing clinicians being overwhelmed. The Association of American Medical Colleges biannually investigates the number of patients per active physician. Reports published two years ago indicated that the number was higher in neurology (23.429) than in ophthalmology (17.162), cardiovascular diseases (14.717), radiology (11.896), psychiatry (8.544), emergency medicine (7.332), internal medicine (2.758), and is approaching specialties with the highest burnout rates such us urology (32.490) [5]. Thus, the low number of practicing neurologists per patient increases the amount of work, compromises patient care, and exacerbates burnout.

Switching to professional working hours per week, an interesting study concluded that neurologists worked 57.1 hours per week, with 42.3 hours being spent performing inpatient activities. In our neurology department, the average number of professional working hours per week is 59, with a peak of 100 on rare occasions (absenteeism of other colleagues because of medical conditions/vacations or lack of staff) [6].

From a holistic point of view, burnout can be regarded as an indicator of quality and duration of life, given that it has a direct damaging effect on health: overnight shifts, exposure to all kinds of infective agents, irregular and exaggerated effort, lack or inadequate physical exercise, emotional detachment, interrupted meals or maladaptive coping strategies such as excessive caffeine intake or other power drinks, alcohol, and drug abuse. Johann Ludwig Casper, a prominent name in forensic medicine stated that there is no profession with a comparable physical and mental force demand as the medical one, an observation comparable with recent studies [7]. It is also worth mentioning that being on call requires working very fast or accomplishing more tasks being short on time. Very similar ideas are presented in a meta-analysis of 17 studies that in people with high demands, the risk of mortality is 20% higher than in the reference group [8]. Similar opinions are found in a study involving 1.671 American neurologists, where 60.1% of the responders had at least one symptom of burnout [2].

According to the World Health Organisation and International Classification of Diseases, burnout has become 2019 a legitimate medical disorder and has been given its ICD-10 code (Z73.0 - Burn-out state of vital exhaustion). Burnout is a state of chronic stress, that occurs after the body system is repeatedly triggered. It can exacerbate mental conditions like anxiety disorders, depression, and sleep problems. Some authors focused on the cortisol secretion parameters and concluded burnout is a mental syndrome with unique pathophysiology [9]. Moreover, as it often happens, the presence of a disease leads to a higher chance for another one to develop. Burnout influences not only subjective well-being but other biological processes as well. In a large study of nearly 9000 employed adults, was found that burnout is a significant risk factor for developing coronary heart disease and finally, heart attacks [10]. These findings support the idea that physicians with high demands as neurologists are exposed to challenges regarding their health and are more vulnerable to stress and burnout.

There is an excessive workload and clerical duties, including finishing notes, phone calls, ordering tests and reviewing results, responding to phone calls and patient requests, and prescribing medication. Assessing indicators related to burnout in a national survey on 9561 neurology residents and fellows after studying 354 responses to the survey the following was revealed: regarding the amount of time spent on clerical tasks directly related to patient care" only 26.2% of residents and 29.7% of fellows agreed that it is reasonable [2]. Another particular challenge is finding meaning in work and this often translates to helping others. Some neurological disorders do not come with treatments or cures or are associated with a significant burden of disability. In the same study, in the matter of, satisfaction with the job" only 68.9% of residents and 63.1% of fellows were more likely to be satisfied with their career choice and in line with, work being meaningful", 78.8 % of residents and 85.6% of fellows had positive feelings towards their job [11]. In comparison to attending physicians, an important number of neurology residents experience burnout due to extra workload and the challenges that come with a new environment, 73% of residents mentioned at least one symptom from the constellation of burnout. Furthermore, both residents and practicing physicians are affected by the second-victim phenomenon, which refers to feelings of guilt caused by medical errors which result in poor patient outcomes [12,13].

Some authors focused instead on sources and outcomes of burnout, on potential interventions to treat it or to prevent the onset. It must be mentioned that burnout is a consequence of systemic deficiencies rather than a result of poor uncoping skills. Increasing trainee resilience and cutting clerical tasks through hiring administrative workers or through using user-friendly technology [14], positive reinforcement and support during residency, and implementing regular burnout evaluations such as Maslach Burnout Inventory. The last one mentioned is the most widely accepted evaluation of burnout and outlines three key aspects of this response: the state of feeling emotionally worn out, feelings of cynicism toward work, and a personal sense of inefficiency in the workplace [15].

The supply-and-demand issue that perpetuates burnout and challenges patient care in neurology could be overcome by recruiting other medical staff. For example, nurse practitioners could get in charge of some medical tasks, without actually exceeding their abilities, as the healthcare oath foremost promotes abstaining from all intentional wrong-doing and harm. This topic with potential usefulness has already been addressed in an article published in the JAMA journal, but it aroused a lot of controversies [16]. Most complaints came from those in need of help, like physicians, stating that to figure out the pathology, prove competency, and be able to give medical assistance one has to go for over a decade in training. This amount of time is spent in school only by doctors, to fully become licensed, and no other alternative shorter programs can replace this training. But maybe they can approach it. An answer to this problem could be by enhancing nonphysician practitioners in medical student courses or by attending residents, giving them templates and free access to educational programs. In conjunction with this, in the UK for example, specialist nurses are known for their crucial role. They can choose and qualify for various neurological conditions (multiple sclerosis, Parkinson's disease, and epilepsy). Sometimes they can order tests, administer basic treatments, and in some states even prescribe medications.

Another indicator of burnout and shortage of neurologists is also projected by the difficulty in making an appointment for new patients and by lengthy waiting lists. Data from 626.000 first appointments scheduled in 2016 with 1.044 providers concluded that wait times for new patients are longer for high-demand specialties, with neurology patients waiting approximately 32.3 days for first appointments [17]. This is particularly relevant since waiting for more than a month often determines patients to cancel their appointments, and never return to the clinic with consequences resulting from delayed diagnosis and treatment. Moreover, significant information was revealed by 2021 research on NHS data conducted by Neurological Alliance – a coalition with over 80 organizations including the MS Society, Parkinson's UK, and MND Association. Thus, they showed that by the end of March 2021, over 150.000 people were waiting for an assessment by a specialist and over 10.000 of these have been waiting for over a year [18]. These numbers indicate how overwhelmed are the neurology services, putting a lot of pressure on existing physicians, and prolonging a state of excessive stress and fatigue that is burnout.

As a consequence of different workplace stressors and poor coping mechanisms, it was estimated that 10-15% of doctors will develop a problem with substance addiction at some point in their careers [19]. Regarding the neurology field, in a published survey among all specialties, answers from 470 chronic pain/neurology subjects as well, it was shown that in this category of physicians there is a prevalence of 3.7% marijuana use. The issue is not limited to illegal drugs, pain medicine, and alcohol count as well. The anonymous questionnaire indicated a prevalence of 88.6% of alcohol use in physicians from the category of chronic pain/neurology, also being the group with the highest prevalence for benzodiazepine of 15.5%. In addition to this, they found 16.3% prevalence for minor opiates and 1.9% for major opiates, hence being ranked the third specialty. Neurologists frequently come across chronic pain patients in need of benzodiazepines and opiates and somehow this exposes them to these drugs. They ranked second only to psychiatrists in the matter of the risk of using benzodiazepines [20].

Many neurologic diseases require interdisciplinary care and this sometimes creates the setting for conflict between providers offering healthcare services [21]. To reduce the burnout burden, neurologists should try to understand and develop the concept of teamwork. Literature describing the issue of individual vs. teamwork in neurology is scarce, but limited evidence suggests there are more benefits from the adoption of a teamwork approach, where feasible. By avoiding professional isolation, rethinking professional roles, and abandoning territorial behavior.

Receiving complaints is another issue that lies at the heart of burnout in neurology as well. Many of these complaints arise from the limits that go along with disabling or cureless illnesses, giving a false feeling that the healthcare workers did not do anything possible to resolve the case. This situation can be overcome by improving the informative part of the medical act with better communication skills with the patient and through offering honest expectations for patients and their families. Moreover, it is not uncommon that patients to have a low level of medical education and not understand the limits of medicine, priorities, or medical procedures, so this is another important factor that promotes complaints [22,23].

We propose some strategies for the prevention of burnout on neurology specialists (Table 1). There are three categories of factors: related to patient education, related to the workplace, and the healthcare system, and factors related to patient education. An important contributor that fuels burnout is the offering of patients by medical professionals who come across neurological diseases in their practice and whose residency programs do not provide minimum knowledge. Many of these patients have functional neurological disorders which do not always require neurologist interventions. The same problem is with incidental findings on brain imaging such as minimal white matter changes with the improbability of multiple sclerosis or other significant CNS diseases. Poor medical knowledge, not understanding the limits of medicine, medical priorities, or investigations are factors of complaints between relatives. Time-consuming work, the complexity of neurological diseases, communicating a difficult diagnosis, or spending more time doing bureaucratic tasks than caring for patients, all of these are frustrating. Adequate working conditions, generous salaries, creation of functional interdisciplinary teams, filling vacancies, and introduction of telemedicine and artificial intelligence in the field of neurology, would be some solutions for attracting young doctors to this specialty.

Table 1: Significant factors contributing to burnout among neurologists and strategies for prevention

Main factors related to burnout	Proposed solutions
Factors related to the patient education	
Many referrals to neurology that do not need neurology intervention Eg: Functional neurology (often, patients with functional conditions tend to show more dissatisfaction) [22].	Educational initiatives/ online courses targeting other medical professionals that send patients and have minimal to no knowledge of common neurological diseases. Early neuroscience curricula in medical school.
The pandemic of cardiovascular risk factors: high blood pressure and cholesterol, obesity, smoking, and poor diet - put a person at high risk for neurological diseases as well.	Preventive medicine. Screening programs and campaigns to raise awareness.
Factors related to the workplace and healthcare system	
Complaints from patients/families arise from: - the poor medical knowledge - not understand the limits of medicine, medical priorities, or investigations (23)	Legal assistance for the doctors involved.
Shortage of neurologists because of not choosing the specialty [24].	Programs in medical school promote and value neurology. Adequate salary.
Neurologists choose urban over rural settings [25].	Improving rural health settings. Providing medical tools/gadgets/making technology available so the rural residents have equal opportunities to receive medical treatment.
The complexity of neurological diseases creates a job mismatch.	Development of team-based neurologic care Increased need for subspecialty medical care Eg: In Romania, there are no specialists in movement disorders or neuro-ophthalmology
Responsibility fatigue at the workplace.	The schedule of work must be dependent on the complexity of the tasks.
The neutral attitude of the hospital management board [26].	Providing support, understanding human needs, expand vacation policies.
Many rescheduling of appointments decreases physician and healthcare system efficiency overall.	Telemedicine and e-consults increase the capacity to respond to the demand for care and help patients with difficulties in coming to their clinic visits [27].
Mounds of paperwork - spending more time doing bureaucratic tasks than caring for patients. Lack of access to medical records - especially in older patients with many investigations.	Digitalization and artificial intelligence are the future of healthcare. Enabling tracking system for ordered tests/ follow-ups.
Time-consuming tasks. Eg: documenting a history of falls in Parkinson	Artificial intelligence Eg: smartwatches or other wearables that quantify falls or periods of inactivity and already provide a pattern or a conclusion.
Factors related to the physician	
Communicating a difficult diagnosis (often the first interaction occurs already at the time of critical illness).	Programs/Training courses that will help doctors improve their medical communication with patients.
The emotional burden of the specialty itself.	Providing necessary psychological assistance to guide neurologists facing mental health problems like depression or anxiety.

CONCLUSIONS

Overall, burnout can be regarded as a matter of specialty, and it has built up slowly over time, creating a vicious cycle, perpetuated by workforce dropout or choosing other medical specialties with a better lifestyle. Identification of burnout effects in neurology is policy relevant for some reasons: it affects the overall healthcare system with all its components, work-life integration (family), emotional and physical well-being, and social engagement. To conclude, it must be regarded as a worldwide issue.

Abstract: *Background: Infection and sepsis represent major complications after abdominal surgery for secondary peritonitis. Finding new tools that can help identify patients at risk for developing postoperative complications is of the utmost importance for clinicians. We tried to evaluate the use of different biomarkers in evaluating the postoperative prognosis of patients with secondary peritonitis. Methods: We searched the available literature on the usefulness of serum biomarkers in evaluating prognosis in patients with secondary peritonitis. Results: Elevated postoperative lactate levels and high procalcitonin (PCT) levels were associated with negative outcomes. C-reactive protein values increase rapidly in response to the surgical insult but have no value in assessing the overall prognosis. Conclusion: Procalcitonin (PCT) is superior to other biomarkers in predicting severe septic complications and overall mortality in patients with secondary peritonitis.*

Keywords: *biomarkers, peritonitis, C-reactive protein, lactate, procalcitonin, presepsin*

INTRODUCTION

Secondary peritonitis is a condition caused by the spread of bacteria and contents of intraabdominal organs into the peritoneal cavity [1] and is the second leading cause of sepsis in intensive care units worldwide [2]. Overall mortality is 6%, but mortality rises to 35% in patients who develop severe sepsis [2]. Secondary peritonitis requires immediate surgical intervention but after the initial procedure, persisting or new-onset abdominal sepsis continues to be a major problem in the postoperative course [3].

Using clinical symptoms such as fever, tachycardia, tachypnea, non-specific laboratory findings, and scoring systems are valuable tools to assess overall severity and prognosis but will not allow a differentiation between an infectious and non-infectious etiology of a systemic inflammatory response. The clinical assessment of sepsis biomarkers has gained considerable interest in identifying patients at risk for severe complications following surgical intervention for secondary peritonitis [1].

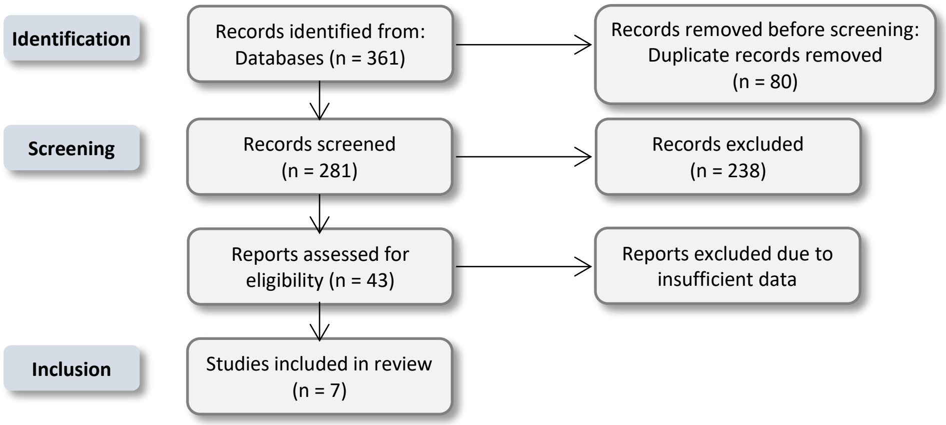
This review aimed to identify the most important biomarkers evaluated in patients with secondary peritonitis and their association with prognosis.

MATERIALS AND METHODS

We searched in three databases using the keywords „peritonitis“ and „prognosis“ in the title or abstract AND specific biomarkers by full name and abbreviated form in full text: lactate, C-reactive protein (CRP), procalcitonin (PCT), presepsin.

Due to the scarcity of the results, a broader search was conducted using the keywords „peritonitis“ AND „biomarker“ to ensure that all relevant literature is covered. The search was last updated on 24/06/2022. A total of 361 publications were primarily retrieved in PubMed, Embase, and Web of Science. No articles were added after manually searching major scientific journals and other references. After excluding 80 duplicates, 281 titles were screened for eligibility and 43 articles were assessed for full-text evaluation. Only English-written human studies were accepted and most articles were excluded due to irrelevancy. We focused only on circulating biomarkers for prognosis in secondary peritonitis. No cut-off point was set for the date of publishing due to the paucity of articles. At the end of the process, seven articles were included in the review. The search strategy is detailed in Figure 1.

Figure 1: Search strategy – identification of studies via databases and registers



Identification

OVERVIEW OF THE SELECTED ARTICLES

Seven articles were included in the current review. Four studies were prospective and three were retrospective, and one study included a control group. Biomarkers of interest were lactate, procalcitonin, and C-reactive protein. No study evaluating presepsin was identified. All studies focused on mortality and severity of septic shock induced by secondary peritonitis.

Further details on the selected studies are summarized in Table 1.

SERUM BIOMARKERS CORRELATED WITH PROGNOSIS IN SECONDARY PERITONITIS

Lactate

Lactate is the metabolic end product of anaerobic glycolysis. Approximately 1500 mmol of lactate is produced daily in all tissues, but mostly in skeletal muscle, brain, intestine, and red blood cells [6,9]. The concentration of arterial lactate is a reflection of the delicate balance between net production and clearance. Disturbances in lactate production, clearance, or both lead to hyperlactatemia and it is seen in a variety of conditions such as sepsis, shock, cardiac arrest, tissue hypoxia, burns, or after some pharmacological agents [6].

The prognostic value of lactate in patients with secondary peritonitis was evaluated in four studies. Negi et al. conducted a prospective study to evaluate the utility of arterial lactate measured on admission (AL1) and 24h after surgery (AL24) as well as lactate clearance as prognostic indicators for mortality in patients with secondary peritonitis. The study concluded that mean values of initial lactate, postoperative lactate, and percentage lactate clearance correlated significantly with higher morbidity and mortality [6]. Of these three lactate indices, postoperative lactate (AL24) was the most accurate in predicting morbidity and mortality [6]. Elevated lactate levels persisting postoperatively probably indicate irreversible pathophysiological changes and global tissue hypoperfusion, indicative of poor lactate clearance and higher morbidity and mortality. Andreevich et al., after conducting a retrospective study, concluded that increased lactate levels both before and 72h post-operatively were associated with a negative prognostic[8]. In the study conducted by Suarez-de-la-Rica et al., 24h postoperative lactate concentrations predicted mortality in the Surgical Critical Care Units, but overall mortality was predicted better by concurrent high procalcitonin and lactate peak concentrations [7].

Jung et al. conducted a retrospective study that aimed to compare the performance of the qSOFA score alone with a combined score derived from qSOFA and serum lactate levels for predicting in-hospital mortality for patients with secondary peritonitis. The study results showed that the qSOFA score alone has poor sensitivity and a modest predictive performance in patients with secondary peritonitis [5]. The addition of one point for hyperlactatemia (plasma lactate level > 2.0 mmol/L) resulted in improved sensitivity (5). The use of the qSOFA + lactate score can be useful to assist clinicians in immediately assessing the risk of mortality in patients with secondary peritonitis [5].

Most studies agreed that elevated post-operative lactate levels correlate better with negative outcomes than preoperative lactate levels.

Procalcitonin

Procalcitonin (PCT) is the 116-amino acid pro-peptide of the biologically active hormone calcitonin [10]. The clinical value of PCT assessment in infection and sepsis has been investigated in almost every medical discipline so far. Most studies have shown that, in general, only in the presence of systemic host response to bacterial or fungal stimuli, does PCT concentration rise above the reference range of 0.5 ng/mL. However, new data demonstrated an early production of PCT related to tissue damage after trauma and the magnitude of the hypovolemic challenge, yet unrelated to infection (4, 10). We analyzed four studies on the usefulness of PCT measurements in predicting negative outcomes in patients with secondary peritonitis. In 246 patients with intraoperatively proven secondary peritonitis of various origins, Reith et al. showed that PCT is a sensitive parameter for the prediction of severe septic complications. Moreover, the study demonstrated that PCT reflects the effectiveness of the surgical procedure in eliminating the septic intra-abdominal focus in the postoperative course (4, 10). PCT was of excellent prognostic value and achieved a sensitivity of 84% and a specificity of 91% in discriminating survivors from non-survivors within the first four postoperative days [4]. Similar observations have been reported in a study conducted by Rau et al. on 82 patients with intraoperatively proven secondary peritonitis. Pro-calcitonin values were elevated in patients who developed septic multiple organ dysfunction syndromes (MODS) with peak levels on the third and fourth days after the onset of symptoms. Comparing the preoperative and postoperative courses, PCT concentrations were significantly elevated in patients with septic MODS during the immediate postoperative course. A persistent procalcitonin elevation beyond the first week after the onset of symptoms was evident in non-survivors, whereas normal concentrations were measured in survivors [3].

Table 1: Studies focused on mortality and severity of septic shock induced by secondary peritonitis

Author	Study design	Biomarker	No. of patients	Correlation with prognosis
Akcay et al (2014)	prospective	procalcitonin (PCT), C-reactive protein (CRP)	84	Serum PCT levels follow a falling trend after surgery as long as the postoperative course remains uneventful. PCT was a better marker than CRP in following postoperative complications and overall prognosis.
Reith et al (2000)	prospective	procalcitonin (PCT), C-reactive protein (CRP)	246	A reduction in the PCT concentration correlated with improvement in the infection and sepsis and was found in all surviving patients. Compared with the values for CRP, PCT showed significant differences between survivors and patients who died, while CRP did not [4].
Rau et al (2007)	prospective	procalcitonin (PCT), C-reactive protein (CRP)	82	The cumulative analysis of all PCT and CRP values measured in the first, second, and third to fourth weeks identified persisting PCT levels greater than 1 ng/mL as an excellent means to assess the overall outcome. Irrespective of the interval, PCT was significantly better than CRP in assessing overall prognosis [3].
Jung et al (2018)	retrospective	lactate	457	The qSOFA score alone has poor sensitivity and a modest predictive performance in patients with secondary peritonitis. The addition of one point for hyperlactatemia (plasma lactate level > 2.0 mmol/L) resulted in improved sensitivity. The use of the qSOFA + lactate score will assist clinicians in immediately assessing the risk of mortality in patients with secondary peritonitis [5].
Negi et al (2020)	prospective	lactate	224	Mean values of initial lactate, postoperative lactate, and percentage lactate clearance were found to correlate significantly with higher morbidity and mortality in patients with secondary peritonitis. Of these three lactate indices, postoperative lactate was the most accurate in predicting morbidity and mortality [6].
Suarez-de-la-Rica et al (2014)	retrospective	lactate, C-reactive protein (CRP), procalcitonin (PCT)	221	Both PCT and lactate provided early prognostic information, more accurate than clinical scores, for overall mortality [7].
Andreevich et al (2021)	retrospective	lactate, C-reactive protein (CRP)	136	Increased lactate and CRP values both before and 72 h after surgery were associated with negative prognostic. PCT value before surgery was insignificant and only an increase in PCT 72h after surgery was associated with a negative outcome [8].

In a prospective study conducted on 84 patients, Akcay et al. were able to demonstrate that serum PCT levels follow a falling trend after surgery as long as the postoperative course remains uneventful. In addition, they showed that after the surgical intervention PCT was a better marker than CRP in following postoperative complications and overall prognosis in patients with secondary peritonitis [1].

Suarez-de-la-Rica et al. compared the prognostic value of lactate, procalcitonin, and c-reactive protein. Peak lactate (>1,8 mmol/L) and PCT (>100 ng/mL) concentrations were associated with mortality, but peak PCT level was the best biomarker for overall mortality. In this study, concomitant high peak lactate and peak PCT concentrations considered as a single dummy variable were highly predictive of overall mortality [7].

C-Reactive Protein

C-reactive protein (CRP), named for its capacity to precipitate the somatic C-polysaccharide of Streptococcus pneumoniae, was the first acute-phase protein to be described [11]. CRP is an evolutionarily conserved protein. From arthropods to humans, CRP has been found in every organism where its presence has been sought [12].

C-reactive protein is a useful marker of systemic inflammation without discriminating infection from other inflammatory processes [7]. When it comes to the value of CRP in evaluating prognosis in patients with secondary peritonitis, after searching the available literature, we found five studies that included this biomarker. All studies agreed that measured CRP values, which increase rapidly in response to the surgical insult, had no value in assessing overall prognosis. C-reactive protein did not reveal any differences between patients with or without septic MODS or in non-survivors and survivors in the perioperative course [3].

CONCLUSIONS

Although a multitude of biomarkers is elevated in patients with secondary peritonitis in the perioperative course, only a few are reliable parameters for assessing the course and prognosis in this category of patients. Many studies have clearly shown that procalcitonin (PCT) is superior to other biomarkers in predicting severe septic complications and overall mortality. In combination with careful clinical patient assessment, PCT offers distinct advantages for the evaluation of response to treatment and prediction of outcome in patients with secondary peritonitis. In regards to the fact that procalcitonin is a well-known „sepsis“ parameter, this may not embrace the real properties of PCT, which remain to be defined.

Further studies must be conducted to obtain more knowledge about the importance of serum biomarkers in patients with secondary peritonitis and their correlation with prognosis.

Conflicts of interest and sources of funding

The authors declare no conflict of interest.

Abstract: *Introduction: As general population tends to have increasing life expectancy, the risk associated with developing chronic kidney disease (CKD) with multiple incapacitating concequences, also increases. Method: For the present study, we registered the data from the observation files of 37 patients diagnosed with CKD undergoing treatment by chronic hemodialysis and noted the CKD associated diagnoses included in the notion of comorbidities. We monitored their statistical incidence both in the whole group and separately, in women and men using TTEST and CORREL. Results: The median age of the subjects was 55.86 (± 12.00) years. The study population mean weight was 74.90 (± 14.44) kg, with a mean weight of 69.33 kg for female subjects, and 77.92 kg for males, respectively. Diabetes was identified in 35.13% of patients, whilst heart failure was present in 16.21% of patients. Conclusions: Following the analysis of the information about the patients with CKD in the dialysis program, which we included in the study group, we observed the existence of variations that occur with age, significant correlations between age and weight and between albuminemia and weight. The most common comorbidity is high blood pressure followed by anemia.*

Keywords: *chronic kidney disease; chronic hemodialysis patients; comorbidities; plasma albumin*

INTRODUCTION

Chronic kidney disease (CKD) can develop due to a multitude of pathologies that all have in common the evolution to kidney failure, with gradual or rapid loss of the main function of the kidneys, that is to remove waste products and excess fluid from the body [1]. The last stage of the development of CKD, especially in patients who are treated by peritoneal dialysis or hemodialysis, is characterized by multiple organs and systems damage [2].

Not only CKD, but also the treatment of its various manifestations, mainly affect the body tissues and systems, at all levels: nervous, cardiovascular, respiratory, endocrine, hematopoietic, digestive, renourinary [2].

The tendency to increase life expectancy of the population is also associated with an increase of the incidence and prevalence of CKD, considering the already known relationship between aging and decreased kidney function, which is seen as a consequence of the physiological aging of the kidneys [2,3]. An even steeper increase in the number of patients with CKD is expected in the coming years. In this context, the medical goal becomes to slow down the progression to terminal stages, achievable primarily by diagnosing the condition as early as possible [1].

Compared to conservative treatment, extrarenal treatment methods provided clear advantages for patients with chronic end-stage renal disease, the duration and quality of life being considerably superior. There are several methods of extrarenal purrification: peritoneal dialysis, hemodialysis, hemodiafiltration. The decision for each type of treatment is based primarily on medical considerations, depending on the underlying disease and the comorbidities present [4]. Diabetic patients are usually at higher risk of developing more severe forms of chronic diseases (e.g. cancer) [5,6,7]. Peritoneal dialysis is preferred for diabetic patients with CKD as this method of treatment ensures the maintenance of a residual diuresis for a longer time, the prevention of complications due to the present vascular damage, the possibility of intraperitoneal administration of insulin and a better hemodynamic stability than chronic hemodialysis. In cases where the patient has a poor state of hygiene or if peritoneal dialysis does not allow a satisfactory volume control to be maintained, chronic hemodialysis is preferred [4].

MATERIALS AND METHODS

For the study we performed, we registered the data from the observation files of 37 patients diagnosed with CKD undergoing treatment by chronic hemodialysis, in the Nephrology Department of the Bucharest University Emergency Hospital.

We noted their general data and the presence of associated comorbidities, as well as the determined values of plasma albumin concentration.

The statistical data processing regarding the incidence of comorbidities revealed important information for understanding the clinical and biochemical context of this particular type of patient in the hemodialysis department.

Among the tests performed on the patients that had presented for chronic dialysis, we noted the value of plasma albumin concentration, because it is a parameter that provides information about the loss of protein in the urine and the nutritional status of renal patients. We determined the statistical differences between the values from women and men, as well as the correlations between this parameter and age, respectively weight.

We performed the statistical processing using the Student test (t-test) to determine the statistical significance of the differences in the values of the parameters determined in women and men and the Correl test to determine whether there are correlations with statistical significance between the parameters we tracked.

We noted the diagnoses associated with CKD, included in the notion of comorbidities and we monitored their statistical incidence both in the whole group and separately, in women and men.

RESULTS

In terms of gender distribution, of the 37 patients, 13 (35.13%) were women and 24 (64.86%) were men.

The median age of the subjects was 55.86 (± 12.00) years. For the women, the median age was 56.46 (± 10.86) years, whereas for the men it 55.54 (± 12.78) years. Although there is a slight gender difference regarding age, this failed to be statistically significant (p> 0.05).

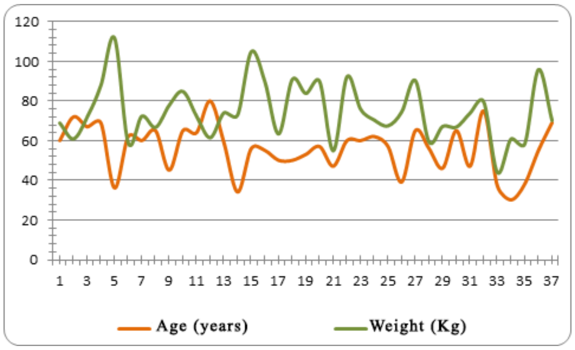
Regarding weight, as presented in Table 1, the study population mean weight was 74.90 (± 14.44) kg, with a mean weight of 69.33 kg for female subjects, and 77.92 kg for males, respectively. As presented in Table 1, this difference was found to be statistically significant, p = 0.01.

Table 1: Average weight and the statistical difference between men and women

	Average weight in women (kg)	Average weight in men (kg)
Average value	56.46	52.27
Standard Deviation	10.87	17.16
p (t-test) 0.43		

Applying the Correl test, we observed that age and weight are two parameters that correlate statistically significantly (p = 0.04) (Figure 1).

Figure 1: Significant correlation between the values of weight and age



For the 37 patients, we noted the value of the plasma albumin concentration and determined the difference in values according to the gender of the patients and the statistical significance of this difference, using the Student test (t-test) (Table 2).

It is observed that the albuminemia values that were determined in these patients are not outside the normal laboratory limits of 3.5-5.2 g/dl (Table 2). By applying the

Correl test, we calculated the statistical significance of the correlations of albuminemia with age and weight (Table 3).

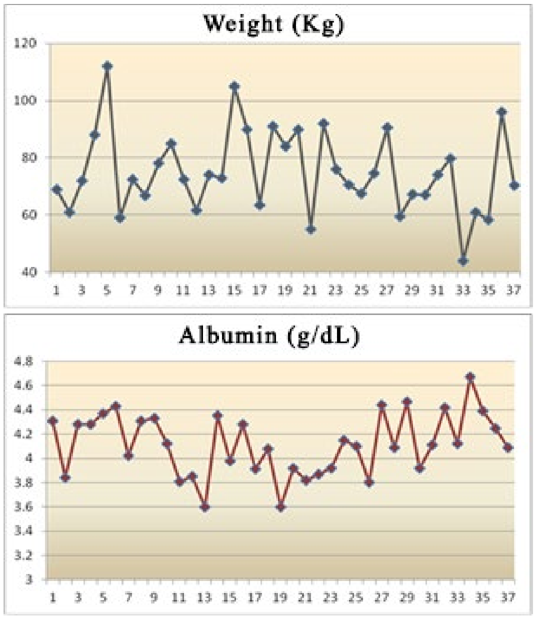
Table 2: Statistical significance of differences in plasma albumin concentrations in patients in the group by sex

Albuminemia(g/dl)		
	Women	Men
Average value	4.10	4.25
Standard deviation	0.24	0.27
t-test	p = 0.41	

Table 3: Statistical significance of correlations between plasma albumin concentrations with age and weight in patients in the group and by sex

Significance of the correlation between plasma albumin concentration and		
	Age	**Weight**
Women	p = 0.1	p = -0.2
Men	p = -0.37	p = 0.1
Total	p = -0.24	p = 0.02

Figure 2: Correlation weight-albuminemia



We observed that separately, in women and men, the plasma concentrations of albumin do not correlate significantly with age or weight, but, after using the Correl test for the whole study group, a significant correlation between albuminemia and weight has been identified.

We made this determination, knowing that the albumin dosage is a test to assess the general state of nutrition, especially in elderly patients with various conditions, in this category falling most of the patients with CKD in the lot we studied.

COMORBIDITIES DIAGNOSED IN THE STUDIED GROUP

Diabetes mellitus, dyslipidemia, atherosclerosis, hypertension, arteriopathy obliterans of the lower limbs

Diabetes is present in 35.13% of patients, 3 of women and 10 of men, which means 23.07% and 41.66%, respectively. Dyslipidemia occurs in a number of 3 male patients, which means a percentage of 8.1% of the total group. Atherosclerosis is noted in a female patient with kidney disease and in 9 male patients, the incidence rate being 27.02% in the whole group. High blood pressure is a more common comorbidity in patients in the study group: 11 out of 13 women are hypertensive and 23 out of 24 men with CKD are hypertensive. Lower limb arteriopathy is present in only 2 of the male patients, which means 5.4% of the group. Both patients also have diabetes and high blood pressure.

Heart failure, cardiomyopathy, arrithmia, valvulopathy, chronic coronary heart disease

Heart failure is present in 5 of the women and only 1 of the men, this comorbidity is therefore found in 16.21% of patients. Cardiomyopathy is rarer, 1 female patient and 2 of the men in the group, ie 8.1% also have this diagnosis. Arrhythmias are more common in women, 5 out of 14, ie 35.7%, presenting this manifestation in the form of atrial fibrillation with medium or large ventricular allure or in the form of supraventricular tachycardia. Among men, only 2.33% have atrial fibrillation with a medium ventricular allure. Thus, 18.91% of the total group have a form of arrhythmia. Valvular damage is identified in 4 patients out of a total of 37, ie 10.81%, more frequently in women 3 out of 14 and only in 1 male patient. Coronary ischemic disease is diagnosed in 3 women and 6 men, the incidence being 24.32%.

Diabetic/hypertensive/mixed nephropathy, chronic tubule-interstitial nephropathy, autosomal dominant polycystic kidney disease, single kidney, chronic pyelonephritis, chronic glomerulonephritis

Chronic tubulointerstitial nephropathy is diagnosed in a single male patient. The incidence at group level is 2.7%. Out of 13 women in the group, hypertensive nephropathy is present in 2 and diabetic nephropathy in 3 of them, a total of 38.46% with nephropathy. Of the 24 men in the group, 6 have diabetic nephropathy, 4 have hypertensive nephropathy and 2 have mixed nephropathy, a total of 50% of patients with nephropathy. A number of 4 of the 13 women, 30.76%, are also diagnosed with autosomal dominant polycystic kidney disease. Of the 24 men, 4 also have this diagnosis, representing

16.66%. At the level of the whole group, the percentage is 21.62%. Only one male patient has a single kidney, the cause being congenital. The incidence at group level is 2.7%. And pyelonephritis rarely occurs, only one patient, a woman, has this diagnosis. The incidence at group level is 2.7%. More common is chronic glomerulonephritis, which is present in 6 of the men, respectively 25%, and in 2 of the women, respectively 15.38%, with an incidence in the whole group of 21.62%.

Kidney stones, parathyroidectomy, secondary hyperparathyroidism, anemia, chronic viral hepatitis

Kidney stones are present in 2 women and 3 men in the group, which means an incidence of 13.51%. Secondary hyperparathyroidism is diagnosed in only 2 patients, a man and a woman, the incidence is 5.4% in the whole group. Surgical removal of the parathyroid glands was performed in 3 women and 1 man in the group, the frequency being 10.81%. Anemia is more common, 7 of the 13 women, ie 53.8% and 15 of the 24 men, ie 62.5%, have pathologically low hemoglobin. Out of the whole lot 59.45% of patients have anemia. Chronic hepatitis B infection is uncommon as viral hepatitis B is present in 2 women, 1 man in the group is infected with hepatitis B virus and 1 is coinfected with hepatitis B + C viruses. The frequency of chronic viral hepatitis in the group is 10.81%.

DISCUSSIONS

Gender and age are factors that influence some characteristics related to CKD in patients with type 1 or type 2 diabetes, and certain particular aspects of pathogenesis, diagnosis and treatment management have been identified, but the mechanisms are incompletely known and more studies are needed to clarify these connections which would be very useful in order to reduce the number of cases of renal patients and to prevent or control the complications of this condition. Considering the data published by Eriksen O. et al. [5], old age and the male gender are predictors of worsening kidney disease and the rapid progression to severe kidney failure. In the study of Giandalia A et al. [8] the authors concluded that men are more affected, because in their studies, the number of men enrolled is higher than the number of women, results similar to our study where the percentage of men was 64.86%.

Weight is an important parameter in assessing the nutritional status of the patient with CKD. In obese people with CKD, the progression of the disease to renal failure is faster compared to cases of normal weight. Also kidney transplantation or hemodialysis, which may become necessary in advanced stages of the disease, may be more difficult and may have more frequent complications in obese people [9]. After initiating treatment with hemodialysis or peritoneal dialysis, in patients with a glomerular filtration rate below 35 ml/min/1.73 m^2, in stage 3 CKD, weight loss is a factor that increases the risk of mortality by 54% compared to with patients whose weight remains constant. Even in patients with moderate renal impairment, weight loss should be closely monitored and the patient's nutritional status monitored before dialysis is required [10].

In the final stages of the kidney disease, hypoalbuminemia is common, caused by factors that act simultaneously: reduced liver synthesis, increased degradation and renal loss and the glomerular filter membrane is damaged and becomes more permeable allowing the passage of negative albumin molecules from plasma. In our study we observed that separately, in women and men, the plasma concentrations of albumin do not correlate significantly with age or weight. However, applying the Correl test to the whole group, resulted in a significant correlation between albuminemia and weight. We made this determination, knowing that the albumin dosage is a test to assess the general state of nutrition, especially in elderly patients with various conditions, in this category falling most of the patients with CKD in the lot we studied. According to Haller C. et al. [11] the inflammatory phenomenon in kidney disease is also involved in the pathogenesis of hypoalbuminemia. Inflammation correlates with the risk of mortality, hypoalbuminemia is not in itself a pathogenic factor of renal impairment, but is a major predictor of unfavorable prognosis.

Diabetes mellitus is one of the main negative prognostic factors for chronic diseases [12]. According to Anders HJ. et al. [13] the prevalence of type 2 diabetes and CKD increases the incidence of diabetic kidney disease, also known as diabetic nephropathy. The combination of the two diseases can be in the form of diabetic kidney disease if the kidney damage is the consequence of diabetes, it can be a kidney disease caused by individual mechanism in the diabetic patient or it can be a coincidence of simultaneous occurrence of the two diseases. The involvement of the membrane-glucose cotransporter membrane and hyperglycemia are associated with the activation of the renin-angiotensin-aldosterone system, glomerular hyperfiltration and tubular hyperabsorption occur, which creates a particular situation that requires appropriate treatment. Whatever the mechanism, the patient's evolution is more unfavorable compared to those who have only one of the conditions [13,14]. Our study results for 35,13% of the patients, that were diagnosed with diabetus mellitus type II, found that 69.23% of them have further developed diabetic nefropathy.

In the study of Tsimihodimos V et al. [15] it was shown that lipid metabolism is disrupted in patients with CKD even in the early stages and can be very severe in some cases, further impairing kidney function. The pathogenic mechanisms are not fully understood, but studies show that dyslipidemia is a pathogenic factor for both kidney disease and the associated cardiovascular disease [16]. In our study dyslipidemia was identified in only 8,1% of the patients.

Atherosclerosis sets in early and progresses rapidly in patients with CKD. It usually increases the risk of cardiovascular disease and, as the severity of kidney disease increases, so does the mortality rate, according to Olechnowicz-Tietz S. et al. [17]. In our study population 27.02% were found to suffer from atherosclerosis.

Considering the cardiovascular risk, compared to the general population, patients with CKD, according to the study of Matsushita K et al. [16] have a constant increased cardiovascular events risk. Studies identified that 70% of CKD patients, and up to 80-90% of those on dialysis, are diagnosed with high blood pressure [18,19]. Considering all these data, our studies results that 91.9% of CKD subjects were suffering of/diagnosed with hypertensive disease are consistent with the data in the literature.

As shown in the study of Maric-Bilkan C. et al. [20], in the absence of diabetes, women have a considerably lower risk than men of vascular, microvascular or macrovascular diseases. The opposite trend is observed in diabetic patients: women are at higher risk for these complications. Microvascular lesions that occur in nephropathy, neuropathy, and retinopathy are more common in men. Macrovascular lesions consisting of chronic coronary heart disease, myocardial infarction, peripheral artery damage, and stroke are more common in women. To explain this, the focus has been on sex steroids, which play an important role in regulating heart function. Estrogens are generally considered hormones with cardioprotective effects, and androgens with adverse cardiac effects. But the effects of these hormones on the target organs are complex and different, and the presence of diabetes interferes with the pathophysiological mechanisms that cause vascular damage [14,18,19].

Renal comorbidities are, in part, primary kidney disease that has progressed unfavorably, with the patient reaching the stage of CKD that requires dialysis in order to survive [20]. Another part of these comorbidities is secondary, the pre-existing disease being another. This is the case with nephropathy, which develops during the course of hypertensive disease or diabetes [14]. The percentage of incidence of nephropathy of any etiology in the study population was 45.94%. It is a high percentage, which is explained by the fact that, as we have shown above, diabetes and hypertension are precursors or caused by CKD.

Our results are consistent with literature data showing that 11.2% of patients in a large group of with CKD present with kidney stones. The same study by Chuang TF. et al [21] shows that patients with kidney stones are 1.82 times more likely to develop CKD.

Secondary hyperparathyroidism is found in chronic dialysis patients, the incidence of this comorbidity being reduced by treatments with phosphorus chelators, calcium supplements and calcitriol. As shown in the study of Llach F. et al [22] there are situations when parathyroidectomy is necessary, namely when clinical signs such as persistent hypercalcemia, pruritus, metastatic calcifications appear [23]. In our study hyperparathyroidism was found in only 5,4% of the patients but out of the whole lot, 10.81% of the patients had already been treated with parathyroidectomy. The latter can cause insufficiency of many organs.

Blood characteristics such as blood group or different blood components (eg. lymphocytes) have been linked to chronic diseases or their treatments toxicity [24-27]. According to the study of Ueda N. et al. [28] hemoglobin levels below 12 g/dl for women and below 13 g/dl for men are considered anemia. Iron and erythropoietin deficiency causes anemia in patients with CKD. Hepcidin is a hormone produced by the liver in inflammation or when the body's iron deposits in the form of ferritin or hemosiderin are saturated. Hepcidin binds to and inhibits ferroportin, thereby decreasing the release of iron from the enterocyte and reticuloendothelial cells and decreases plasma iron. Inflammatory status in CKD increases hepcidin regardless of the availability of iron to the body, so it becomes necessary to administer iron, but also to reduce inflammatory phenomena [29]. It was a frequent occurence in our study as 62.5% of our patients were diagnosed with anemia.

Hepatitis B or C virus infections can cause chronic kidney damage but do not have a high incidence according to Chacko EC et al. [30]. If the infection occurs in patients with CKD, anti-infective treatment has many side effects and may worsens the prognosis. Similar results were shown in our study as only 10.81% of the patients presented with concurrent viral hepatitis and CKD.

CONCLUSIONS

Following the analysis of the information about the patients with CKD in the dialysis program from our study weight has been found to be significantly higher in men, compared to women. Albuminemia was within normal limits in all patients, significantly correlating with the body weight. Patients' comorbidities identified in our study were similar to the ones found in the current literature to be related to CKD. The most common comorbidity is high blood pressure, identified in over 90% of the subjects. Anemia is the second most common comorbidity, occurring in almost 60% of patients. With high frequency, in over 20% of patients, we observed the presence of diabetes, atherosclerosis, ischemic coronary heart disease, nephropathy of various etiologies, autosomal dominant polycystic disease and chronic glomerulonephritis.

Abstract: *Coronary CT angiography is a non-invasive method of analyzing the coronary lumen through which the atheromatous bur-den can be evaluated, with the analysis of the type of plaque (soft, calcified, mixed) and the impact on the arterial lumen (stenosis, occlusion). The anatomical evaluation by coronary CT is indicated in symptomatic patients with low and medium risk factors for coronary atherosclerotic disease, in those with inconclusive laboratory and EKG results, patients with un-certain stress test results, in the evaluation of coronary grafts and intrastent stenoses. Depending on the result of the angiography, the severity of the stenosis and the management of the patient are established. In the case of mild and medium stenoses, risk factors management and drug treatment are recommended. For severe stenoses, patients are referred for interventional coronary angiography or functional evaluation. Coronary CT angiography increases the certainty of coronary atherosclerotic disease diagnosis. It has a superior discriminative capacity of plaques with low attenuation, the main predictor of myocardial infarction, with almost five-fold higher risk. Coronary CT angiography increases the adaptation of medication, and the inclusion of statin therapy decreases the risk of fatal and nonfatal myocardial infarction at 5 years and increases the quality of life.*

Keywords: *coronary CT angiography, coronary atherosclerotic disease, calcium score, CAD-RADS*

INTRODUCTION

Atherosclerotic disease is the main cause of death in Europe [1]. Lifestyle factors (smoking, diet, level of physical activity) but also biological risk factors (hypertension, hypercholesterolemia, hyperglycemia) contribute to this [2].

The management of patients with coronary atherosclerotic disease is complex, including numerous investigative methods. Of these, coronary CT angiography has been analyzed more and more, over the last decade, due to technological progress. Coronary CT angiography is a non-invasive method of evaluating the heart and coronary arteries. Coronary CT angiography is performed using a computer tomograph that involves high-speed scans for moving organs and contrast material containing iodine, administered in injectable intravenous form to obtain the best images of the coronary arteries and the heart. Thus, the atheroma plaques in the coronary arteries can be identified, the type of plaques analyzed (soft, calcified, mixed), and the consequences on the arterial lumen (stenoses, occlusions) evaluated. Coronary anomalies can be detected, valve morphology can be analyzed, as well as the degree of myocardial perfusion.

MATERIALS AND METHODS

The main reference studies used in evaluating and managing patients with coronary atherosclerotic disease are extensive studies that have contributed to the current state of knowledge in this field, demonstrating the usefulness of the investigation in diagnosis, monitoring, and recommendations for the treatment of the disease.

The PROMISE study (Prospective Multicentre Imaging Study for Evaluation of Chest Pain) – from the year 2017 – showed that coronary CT angiography is a superior means of evaluation for identifying patients at risk with nonobstructive coronary atherosclerotic disease, compared to classical functional exploration means, in patients with stable angina pectoris and with an average probability of coronary atherosclerotic disease. The patients were randomly divided into two groups, 4500 patients were investigated by coronary CT angiography and 4602 patients were evaluated by functional means (exercise electrocardiogram, exercise ultrasound, and exercise myocardial scintigraphy). The patients were subsequently monitored for 26 months. The significantly lower incidence of coronary events in patients investigated by coronary CT angiography compared to those evaluated by functional means (33.4% versus 78.0%) demonstrates that coronary CT angiography had a significantly higher discriminative capacity for predicting coronary events than functional explorations (c -index, 0.72; 95% CI, 0.68-0.76 versus 0.64; 95% CI, 0.59-0.69; P=0.04) [3].

The SCOT HEART study (Scottish Computer Tomography of the Heart) is large, started in 2010, and is still ongoing, which will continue until 2027, with some of the results already published. It is a randomized parallel study, which included, between 2010-2014, 9848 participants with angina pectoris suggestive of coronary atherosclerotic disease and with mild and medium risk factors. The patients were divided into two groups that were evaluated differently: 4146 patients by coronary CT angiography and the rest were managed by standard anatomical and functional means. The main diagnostic results showed that coronary CT angiography increased the certainty of the diagnosis of coronary atherosclerotic disease (relative risk [RR] = 1.79, 95% confidence interval [CI] 1.62-1.96, p < 0.001) and reduced the frequency of the diagnosis of angina due coronary atherosclerotic disease (RR = 0.93, 95% CI 0.85-1.02, p = 0.13) compared to standard care [4]. The main clinical result was a decrease in the risk of fatal and nonfatal myocardial infarction at 5 years, which was 2.3% in the coronary CT angiography group, compared to 3.9% in the group managed by standard means. The secondary results consisted of an increase in the quality of life, the adaptation of medication, and the inclusion of statin therapy. In those cases where the lesions were severe, patients were referred for angiography and stenting [5].

Other secondary, very important results emerged in 1769 patients, followed for 4-5.7 years, which proved that the presence of plaques with low attenuation is the main predictor of myocardial infarction, independent of the presence of cardiovascular disease risk factors, of the score of calcium or area of stenosis. Patients with low-attenuation plaques had an almost 5-fold higher risk of myocardial infarction (95% CI, 2.06-10.5; P<0.001). In 41 patients who suffered an acute myocardial infarction, both low-attenuation plaque load and calcium score were increased (336 [62-1064] versus 19 [0-217] Agatston units; P<0.001), and the presence of obstructive coronary artery disease (54% versus 25%; P<0.001) [6].

The UK's National Institute for Health and Care Excellence's 2016 NICE chest pain guideline recommended coronary CT angiography as the first line of evaluation in patients with new stable chest pain. Emphasis is placed on anatomic explorations over functional ones, a choice to which cost-effectiveness also contributes [7,8].

However, this approach raised concerns that, after the first evaluation with coronary CT angiography, there would be an increased referral to further investigations, such as invasive coronary angiography. To test this, a retrospective study was conducted on 652 patients who underwent coronary CT angiography from 2017 to 2018. The results showed that 92 patients had moderate (50-70%) or severe stenosis (>70 %). Of these, 69 were directly referred for invasive coronary angiography, of which 63 underwent the investigation, and severe atherosclerotic coronary disease was confirmed in 40 patients (63%). Among the patients with moderate stenosis, 18 were referred to cardiac stress echography, which was positive in one case. The remaining patients had mild stenosis in 62 cases, 36 studies were inconclusive, and the rest of them (462 patients) were normal or had minimal stenosis [9]. The study's conclusions showed that coronary CT angiography is an effective first-line method in the evaluation of patients with newly appeared stable angina pectoris, most of them having normal results or minimal coronary atherosclerotic disease. In patients with severe stenosis, it had an increased detective capacity, the stenosis being confirmed by invasive coronary angiography in 63% of cases.

The positive predictive value for coronary stenosis of coronary CT angiography, compared with stress tests, was evaluated and published in a study from 2019. A total of 800 patients with stable angina pectoris from two centers were included, one in the UK where 400 patients were investigated with coronary CT angiography and a center in Portugal where 400 patients were investigated with exercise tests (treadmill exercise stress test EST or stress imaging test). The patients in the two groups were equally distributed in terms of gender and BMI. Of the 400 coronary CT angiographic examinations, 387 (96%) were diagnostic. Of these, 92 patients (23%) had CAD-RADS 3-5 coronary obstruction, of which 67 (72%) underwent coronary angiography and 61 patients (91%) had atherosclerotic coronary obstructive disease confirmed. In the Portuguese group, 400 patients with stable angina evaluated by stress test with the positive result, recommended for interventional angiography, were included. On interventional angiography, the obstructive coronary disease was diagnosed in 51% of patients. In conclusion, the positive predictive value of coronary CT angiography is 91%, statistically significantly higher (p<0.0001) than stress tests (51%) [10]. The study concludes that coronary CT angiography, due to its significantly higher predictive value than exercise tests, has a good indication as a first test for evaluating coronary stenosis, and could mean the avoiding of unnecessary interventional angiographic tests.

The AGATSTON coronary artery calcium score is a semi-automatic measurement of the degree of calcification of the coronary arteries. It is an investigation performed with a low dose of radiation at the beginning of the coronary CT angiographic examination, before the administration of contrast substance. The main role is an early stratification of the degree of coronary atherosclerotic infiltration.

An automatic calculation of coronary calcifications is made according to the density in Hounsfield units and the area occupied by the plaque.

Depending on the value of the total calcium score, coronary artery disease is divided into five degrees: no evidence of disease (calcium score 0), minimal damage (1-10), mild (11-100), moderate (101-400), severe (>400), the risk of major cardiac events increases in patients with an Agatston score greater than 160 (Table1) [11].

Table 1: Calcium score according to the Agatston scale

Agatston score	Coronary artery disease
0	no evidence of calcium
1-10	minimal
11-99	mild
100-399	moderate
400-999	severe
1000+	extensive calcium deposits increased risk of coronary events in the next year

The calcium score showed a good correlation with coronary CT angiography in the diagnosis of coronary plaques, with the limitation of not being able to evaluate the soft component of the plaque.

Special emphasis is given to the Agatston score of zero, there is the concept of "the power of zero", which means that patients are considered low risk and if there are no other risk factors, that leads to the avoidance of certain preventive drug therapies, such as statins. Another important role of the calcium score is personalizing the prescription of statins and aspirin among the general population but also the population with special conditions such as severe hypercholesterolemia or diabetes [12].

Coronary calcium score (CAC) has become a popular investigation due to its accessibility, speed, tolerability, low cost, reproducibility, and financial benefits due to the exclusion of complex coronary pathologies that involve more expensive investigations [13].

There are practice guidelines that include structured recommendations for the treatment and prevention of coronary atherosclerotic disease but there are some variations between countries in using coronary calcium score as a reference for inpatient treatment. However, there is a common agreement that coronary calcium scoring assessment is to begin in patients over 40 years. In asymptomatic patients with an intermediate risk of atherosclerotic coronary disease and a calcium score of over 100, the initiation of statin treatment is recommended. In patients with a calcium score of 0, the risk is decreased and the administration of statins is retained, with a repeat of the calcium score after 10 years. These conclusions were reached following the MESA study (Multi-Ethnic Study of Atherosclerosis) in which the 10-year risk of cardiac events was between 1.3-5.6% for a calcium score of 0 and 13-26.6% for a calcium score over 300. The MESA study concluded that in conditions of other cardiovascular disease risk factors maintained constant, the relative risk of cardiac events increases proportionally with the increment of the calcium score [14].

For the good management of patients with coronary atherosclerotic disease, the Guide of the European Society of Cardiology (ESC) was updated in 2019. It established coronary CT angiography as the first line of anatomical evaluation of patients with coronary atherosclerotic disease. The previous recommendations (ESC guide from 2013) proposed a combined approach between anatomical and functional means.

The current management of patients with angina pectoris and suspected obstructive coronary disease consists of a 6-step approach.

1. In the first stage, patients are evaluated through a clinical examination to identify patients with unstable angina or acute coronary syndrome, with the determination of symptoms.

2. The second step involves the evaluation of the general condition and the quality of life - patients with unstable angina or acute coronary syndrome are not included.

3. The third step includes performing some basic tests (blood tests, resting electrocardiogram, resting cardiac ultrasound) and evaluating the function of the left ventricle.

4. Step four consists of assessing the risk of clinical probability of obstructive coronary disease.

5. The fifth step involves diagnostic tests, which are chosen depending on the clinical probability of obstructive coronary disease but also multiple clinical factors, comorbidities, expertise, and access to examinations.

Thus, the anatomical evaluation by coronary CT is recommended as an initial diagnostic test in symptomatic patients in whom the coronary atherosclerotic disease cannot be excluded by clinical evaluation, in those with a low and medium probability of coronary atherosclerotic disease.

Functional tests are recommended in situations where coronary CT angiography is non-diagnostic or has shown stenoses whose functional significance is uncertain.

Invasive angiography is recommended for those with very high clinical probability, symptoms that do not respond to drug treatment, and typical angina at a low level of effort, in patients with an uncertain diagnosis on functional tests.

Coronary CT angiography is not recommended in extensive calcifications, irregular heart rhythm, significant obesity, the impossibility of performing respiratory commands, and any other situations in which qualitative images cannot be obtained.

6. The sixth step, depending on the result of the above tests, the management of the patient and the drug treatment are decided.

Severe calcifications and poor clinical images can lead to an overestimation of the severity of stenoses. In patients that present revascularization through stents and bypass grafts, the accuracy of the coronary CT angiographic examination is impaired in some cases due to the presence of blooming artifacts and the incomplete evaluation of the native vessels. Coronary CT angiography is not recommended in any situations in which qualitative images cannot be obtained: extensive calcifications, significant obesity, and the impossibility of performing respiratory commands [15].

CAD-RADS Coronary Artery Disease Reporting and Data System is a method of evaluating coronary atheromatous plaques developed by the American Cardiology Society with the main purpose of standardizing the reporting of coronary atherosclerotic disease.

Also, the method includes recommendations for patient management depending on the result of coronary CT angiography (Table 2).

Table 2: CAD Rads score for the quantification of stenoses and patient management

CAD-Rads	Stenosis	Additional test
0	0%	-
1	1-24% minimum	-
2	25-49% mild	-
3	50-70% moderate	functional evaluation
4A	70-90% in 1 or 2 vessels	functional evaluation or interventional coronary angiography
4B	>50% in the left main trunk >70% in 3 vessels	interventional coronary angiography
5	100% total occlusion	interventional coronary angiography and viability assessment
N	Non-diagnostic study	additional evaluations

Thus, stenoses are divided into 5 categories, as follows:

- CAD-RADS 0 means the absence of plaques or stenoses and implies the search for other causes of angina pectoris;
- CAD-RADS 1 are plaques without stenosis or minimal stenosis (1%-24%) and imply preventive therapy and risk factor management;
- CAD-RADS 2 includes mild stenoses (25-49%) and includes preventive therapy and risk factor management, especially in patients with non-obstructive plaques in several segments;
- CAD-RADS 3 are moderate stenoses (50-69%). Patient management consists of anti-ischemic pharmacological treatment, preventive with the treatment of risk factors;
- CAD-RADS 4 are severe stenoses, which include two sub-categories: A = severe stenoses (70-99%) and B = tri coronary stenoses (≥70%) or left common coronary trunk (>50%). For category A, interventional coronary angiography or functional evaluation is recommended and for category B, interventional coronary angiography is recommended, to which anti-ischemic drug treatment and treatment of risk factors are added;
- CAD-RADS 5 is total occlusion (100%), and interventional coronary angiography and/or viability assessment is recommended, to which anti-ischemic drug treatment and treatment of risk factors are added;
- CAD-RADS N includes non-diagnostic studies that cannot exclude obstructive coronary disease, and require additional/alternative investigation.

All vessels larger than 1.5 mm in diameter must be included in the classification.

CAD-RADS 1 category also includes plates with positive remodeling and no evidence of stenosis.

There are four modifiers of the CAD-RADS score that are mentioned in the result with the "/" symbol, these are 1 N (non-diagnostic), 2 S (stent), 3 G (graft), and 4 V (vulnerability)[16].

RESULTS

The selected studies show that coronary CT angiography increases the certainty of the diagnosis of coronary atherosclerotic disease. It can predict coronary events, decreases the risk of fatal and nonfatal myocardial infarction at 5 years, and increases the quality of life. Coronary CT angiography has a good indication for being the first test for evaluating coronary stenosis due to its higher predictive value than exercise tests, thus avoiding several unnecessary interventional angiographic tests. The management of patients with coronary atherosclerotic disease can be conducted depending on the result of coronary CT angiography. The detection of severe lesions by coronary CT angiography makes intervention possible in the next stage by angiography and angioplasty.

DISCUSSION

The indications for coronary CT angiography are numerous - from retrosternal pain, clarification of inconclusive non-invasive studies, and assessment of coronary atherosclerosis and by-passes or stents.

The management of the patient with coronary atherosclerotic disease involves a clinical examination and basic tests (blood tests, resting electrocardiogram, resting cardiac ultrasound). Anatomic evaluation by coronary CT is recommended as an initial diagnostic test in symptomatic patients with low and intermediate probability of atherosclerotic coronary artery disease. Functional testing is recommended in situations where coronary CT angiography is nondiagnostic or has revealed stenoses of uncertain functional significance. Depending on the severity of the stenosis, the management of the patient is established. For minimal and small stenoses, preventive therapy and the management of risk factors are chosen. For moderate stenoses, anti-ischemic pharmacological treatment is added, and for severe stenoses, interventional coronary angiography or functional evaluation is recommended.

Also, with the help of coronary CT angiography, other structures such as bones, soft tissues, lungs, or blood vessels can be visualized simultaneously during the scan, being useful for a possible differential diagnosis.

There are limitations of coronary CT angiography such as pregnancy or chronic renal failure, and other contraindications: cardiac arrhythmias, hyperthyroidism, and iodine allergy. In patients with revascularization through stents and bypass grafts, the accuracy of the coronary CT angiographic examination can be impaired due to blooming artifacts and incomplete evaluation of the native vessels. Coronary CT angiography is not recommended in any situations in which qualitative images cannot be obtained: extensive calcifications, significant obesity, and the impossibility of performing respiratory commands.

CONCLUSION

Numerous studies have proven coronary CT angiography as the main investigation for coronary anatomical evaluation. Coronary CT angiography provides important information about the presence and extent of coronary atheroma plaques. A major advantage is the early diagnosis of coronary atherosclerosis, based on which preventive treatment can be administered. Coronary CT angiography decreases the risk of myocardial infarction, allows drug treatment adaptation, and increases the quality of life.

Conflicts of interest and sources of funding
The authors declare no conflict of interest.
This research received no external funding.

Authors' contribution
All authors have read and agreed to the published version of the manuscript.
The respective roles of each author are: ASC first/lead author performed the research, wrote the paper, and is the corresponding author, secondary authors DC and SMS supervised the paper, implemented feedback, and conceptualized some ideas.

Ethics approval and consent to participate
The manuscripts contain a study that hasn't been performed on humans, ethical review and approval were not applicable.

Patient consent for publication
Not applicable.

Abstract: *We wanted to evaluate the efficacy of intravenous immunoglobulin (IVIG) treatment in Covid-19 patients in the intensive care unit (ICU). Sixteen (66.7%) male and 8 (33.3%) female adult severe Covid-19 patients who were treated with IVIG in the tertiary ICU between April 2020 and October 2021 at Ankara City Hospital were retrospectively reviewed. The median age of the patients was 63 (interquartile range (IQR):19). The patients were evaluated in terms of laboratory values and clinical results before and after IVIG treatment. There was no statistically significant difference between survived and deceased Covid-19 patients treated with IVIG in terms of age, gender, the onset of symptoms, presence of concomitant diseases, APACHE-II scores, duration of mechanical ventilator support, and length of stay in the ICU. When the laboratory values before and after IVIG treatment were compared, a significant decrease was identified only in alanine transaminase levels (p=0.01). However, there was a statistically significant difference in mortality in 5 patients with Guillain-Barré syndrome who all survived (p=0.001). IVIG treatment was effective in Covid-19 patients with Guillain-Barré syndrome. However, IVIG treatment did not have a statistically significant effect on pre and post-treatment laboratory values, morbidity, and mortality of severe Covid-19 patients in the ICU.*

Keywords: *Covid-19, critical care, Guillain-Barré syndrome, Intravenous immunoglobulin*

INTRODUCTION

Coronavirus disease 2019 (Covid-19) is caused by a RNA virus named Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) [1,2]. Covid-19 can lead to asymptomatic infection, mild symptoms, or severe pulmonary symptoms with hyperinflammation [3]. In severe Covid-19 patients, management of hyperinflammation and cytokine storm with appropriate antiinflammatory agents is recommended [4]. Different anti-inflammatory agents have been tried on critically ill patients during the Covid-19 pandemic.

IVIG is a biological agent which contains pooled polyclonal immunoglobulin G from the plasma of approximately one thousand healthy blood donors [1]. IVIG is used for the treatment of immunodeficiency, autoimmune and inflammatory diseases [5]. IVIG has not only anti-inflammatory effects but also the ability to neutralize bacterial toxins [6]. IVIG treatment has also been tried in epidemic diseases related to viruses such as influenza A H1N1, Middle East Respiratory Syndrome (MERS-CoV-2), and Severe Acute Respiratory Syndrome (SARS), and it has been reported that IVIG treatment decreased viral load, caused clinical improvement and decreased mortality in patients with a severe course [7,8]. In light of experience, IVIG treatment has been recommended to be used for the management of patients with Covid-19 [1,9-13]. However, the role of IVIG treatment in patients with severe Covid-19 remains unclear. Thus, this study aimed to evaluate the efficacy of IVIG treatment administered to severe Covid-19 patients in the ICU.

MATERIALS AND METHODS

Local ethics committee approval for this study was obtained from Ankara City Hospital (E2-21-835). The electronic records of 640 Covid-19 patients who were followed up between April 2020 and October 2021 in tertiary ICU were retrospectively reviewed. Thereafter, sixteen (66.7%) male and 8 (33.3%) female adult Covid-19 patients who were treated with IVIG in the ICU between April 2020 and October 2021 at Ankara City Hospital were included in this study for further analysis. The definitive Covid-19 diagnosis was based on both real-time reverse transcription polymerase chain reaction (RT-PCR) test results and ground glass appearance with pneumonia on thorax computed tomography. These severe Covid-19 patients had also respiratory distress with peripheral capillary oxygen saturation (SPO2) ≤ 93% in room air before admission to the ICU.

IVIG treatment was administered due to sepsis in 6 (25%) patients, Guillain-Barré syndrome in 5 (20.8%) patients, hematological disorders such as hemophagocytic syndrome, chronic lymphocytic leukemia and autoimmune hemolytic anemia in 9 (37.5%) patients, rheumatologic and immunological disorders such as immunodeficiency, systemic lupus erythematosus, myositis and vasculitis in 4 (16.7%) patients. In all patients, IVIG was administered at 0.4 g/kg/day for 3 consecutive days. These 24 patients were evaluated in terms of laboratory values before the first IVIG treatment session and after the third IVIG treatment session. Thus, neutrophil, lymphocyte and platelet count, neutrophil/lymphocyte ratio, lactate dehydrogenase, d-dimer, fibrinogen, ferritin, procalcitonin, c-reactive protein (CRP), interleukin-6, aspartate aminotransferase (AST) and alanine aminotransferase (ALT) values were noted. Demographic data, the onset of symptoms, concomitant diseases, APACHE II scores, duration of mechanical ventilator support, length of ICU stay, and mortality rates were also recorded.

For all statistical analysis, Statistical Packages for the Social Sciences (v17.0 SPSS 24 Inc. Chicago, IL) software was used. Categorical data were presented as numbers and percentages, while quantitative data were presented as mean standard deviation or median and interquartile range (IQR), as appropriate. The differences between the two groups were evaluated with the Mann-Whitney U test and the chi-square test. The statistical significance level was accepted as p<0.05.

RESULTS

The median age of the patients included in this study was 63 (IQR:19), and the median time to symptom onset was 6.5 days (IQR:6). The median APACHE II score of these patients was 16 (IQR:9). The median length of stay in the ICU was 22.5 (IQR:34) days, whereas the median mechanical ventilator time was 19 days (IQR:29) (Table 1). Eighteen (75%) patients had concomitant diseases such as diabetes mellitus type 2, hypertension, and coronary artery disease. The most common disease accompanying Covid-19 was hypertension in 13 (54.2%) patients. The most common symptom was dyspnea in 17 (70.8%) patients. Fever was present in 7 (29.1%) and cough in 5 (20.8%) patients. Other less frequent symptoms were headache, sore throat, nausea, vomiting, impaired taste and smell, myalgia, and weakness. Complications, which were not related to IVIG treatment, such as gastrointestinal bleeding in 2 patients, cerebrovascular accident in 1 patient, myocardial infarction in 1 patient, pneumothorax in 6 patients, and seizures in 2 patients were observed in total in 12 (50%) patients. Antibiotics were empirically administered in 15 (62.5%) of the patients. Unfortunately, 16 (66.7%) patients passed away due to complications related to Covid-19 (Table 1).

Table 1: Characteristics of the Intravenous Immunoglobulin Treated Covid-19 Patients

Characteristics of Covid-19 patients	Survived	Deceased	Total	*P* value
Gender (n, %) Male Female	 6 (75) 2 (25)	 10 (62.5) 6 (37.5)	 16 (66.7) 8 (33.3)	0.67*
Age (years) (median, IQR)	61.5 (29)	63.5 (19)	63 (19)	0.85**
The onset of symptoms (days) (median, IQR)	6.5 (3)	6.5 (6)	6.5 (6)	0.60**
Length of ICU stay (days) (median, IQR)	29.5 (42)	22.0 (23)	22.5 (34)	0.42**
Mechanical ventilator duration (days) (median, IQR)	26 (59)	16 (27)	19 (29)	0.32**
Presence of concomitant disease (n, %)	7 (87.5)	11 (68.8)	18 (75)	0.62*
Diabetes mellitus type 2	4 (50)	4 (25)	8 (33.3)	0.36*
Hypertension	6 (75)	7 (43.8)	13 (54.2)	0.21*
Coronary artery disease	-	5 (100)	5 (20.8)	0.13*
Complications (n, %)	5 (62.5)	7 (43.8)	12 (50)	0.67**
Antibiotic use (n, %)	4 (50)	11 (68.8)	15 (62.5)	0.41**
APACHE II score (median, IQR)	15 (9)	18.5 (12)	16 (9)	0.13**

*†IQR: interquartile range. ‡ICU: intensive care unit; *Chi-square test was used. **Mann-Whitney U test was used*

There was no statistically significant difference between survived and deceased patients in terms of gender, age, the onset of symptoms, length of stay in the ICU, duration of mechanical ventilator support, accompanying symptoms, concomitant diseases such as diabetes mellitus type 2, hypertension, coronary artery disease, complication development, antibiotic use, and APACHE II scores. However, a significant difference was identified in mortality when the effect of IVIG treatment administered for Guillain-Barré syndrome in 5 patients and other disorders were compared (p=0.001). All patients with Guillain-Barré syndrome survived after IVIG treatment. All 6 patients, who were treated with IVIG for sepsis, died. Three patients died and 1 patient survived with rheumatological and immunological diseases. Seven of 9 patients with hematological diseases passed away, whereas 2 patients survived (Table 1). When the laboratory values before and after IVIG treatment were compared, a significant decrease was found only in ALT levels (p=0.01) (Table 2).

Table 2: Laboratory Parameters of Covid-19 Patients Before and After IVIG Treatment

Laboratory parameters	Before IVIG treatment	After IVIG treatment	*P* value*
Neutrophil count x10^9/L	8.4 (6.5)	8.0 (7.8)	0.84
Lymphocyte count x10^9/L	0.59 (0.49)	0.59 (0.45)	0.26
Platelet count x10^9/L	206.5 (152)	210 (142)	0.48
Neutrophil/lymphocyte ratio	13.0 (10.4)	11.8 (7.0)	0.39
Lactate dehydrogenase (U/L)	456.5 (349)	459.5 (193)	0.18
D-dimer (mg/L)	2.79 (4.91)	2.69 (6.05)	0.74
Fibrinogen (g/L)	5.4 (2.9)	4.4 (2.8)	0.22
Ferritin (µg/L)	1011 (1417)	715 (1198)	0.38
Procalcitonin (µg/L)	0.30 (0.35)	0.51 (1.17)	0.10
C-reactive protein (g/L)	66 (136)	95 (151)	0.76
Interleukin-6 (pg/mL)	31.1 (34.3)	38.2 (61.4)	0.40
Aspartate aminotransferase (U/L)	44.5 (50)	40.5 (26)	0.21
Alanine aminotransferase (U/L)	52.5 (48)	34.5 (46)	0.01

*In all patients, IVIG was administered 0.4 g/kg/day for 3 consecutive days. Numerical data are given as a median and interquartile range. IVIG: intravenous immunoglobulin. *Wilcoxon test was used.*

DISCUSSION

The severity of the cases, the IVIG dose, and the time of administration should be considered when evaluating the effect of IVIG on Covid-19. In our study, the patients who underwent IVIG therapy were severe Covid-19 patients and all of the patients received IVIG treatment at the same dose and duration (0.4 g/kg/day for 3 consecutive days).

Huang et al. reported that 45 non-severe Covid-19 patients who were treated with IVIG had no benefit beyond standard therapy in terms of duration of fever, virus clearance time, length of hospital stay, and use of antibiotics [14]. However, after the initiation of IVIG therapy in Covid-19 patients, there have been several studies published reporting that IVIG treatment reduced mortality in Covid-19 patients. Gharebaghi et al. reported that 30 Covid-19 patients were treated with IVIG four vials daily for three days and the in-hospital mortality rate was significantly lower in the IVIG group compared to the control group (6 (20.0%) vs.14 (48.3%), p=0.022) [15]. Sakoulas et al. administered IVIG 0.5 g/kg/d for 3 days to 16 Covid-19 patients, reporting that patients treated with IVIG had shorter median ICU stay (2.5 vs 12.5 days, p=0.006) in addition to improvement of hypoxia compared to the control group [16]. Raman et al. reported that 50 Covid-19 patients were treated with IVIG, who had a significantly shorter hospital stay, and faster recovery with an improvement in oxygen saturation. Moreover, Raman et. al claimed that positive RT-PCR tests of Covid-19 patients treated with IVIG became negative in a shorter period compared to the control group (7 vs 18 days) [17]. Ali et al. administered each group with 10 patients with different doses of IVIG 0.15, 0.20, 0.25, and 0.30 g/kg. Even 10 of 40 participants (25%) passed away, Ali et al. reported that IVIG increased survival chances and reduced the risk of Covid-19 progression [18]. Esen et al. reported that 51 Covid-19 patients who received IVIG had prolonged median survival time and reduced CRP levels [19]. Shao et al. stated that early administration (admission ≤ 7 days) of high-dose IVIG (> 15 g per day) not only improved the prognosis but also reduced 60-day mortality in severe Covid-19 patients [20].

The latest Surviving Sepsis Campaign Guidelines did not recommend IVIG therapy for the treatment of sepsis due to the low quality of evidence from previous studies [21]. All of our 6 patients treated with IVIG for sepsis died, however, all patients with Guillain-Barré syndrome survived after IVIG treatment in this study. In addition, there are several case reports of Covid-19 patients who had neurological disorders such as acute disseminated encephalomyelitis and Guillain-Barré syndrome which were reported to be successfully treated with IVIG [22-27]. Moreover, IVIG treatment has been reported to be effective in Covid-19 related immunological diseases such as multisystem inflammatory disease, myocarditis, and Kawasaki disease [28].

However, there are several studies claiming that IVIG treatment did not affect the need for mechanical ventilation, improvement in chest tomography, and reduction in mortality in severe Covid-19 patients [29]. Tabarsi et al. administered 400 mg/kg IVIG daily for three days to 52 patients, in addition to hydroxychloroquine and lopinavir/ritonavir treatment. IVIG treatment was initiated after 3.84 ± 3.35 days of admission and Tabarsi et al. did not identify any significant difference between the IVIG and control group in terms of the need for mechanical ventilation and mortality [29]. Hou et al. reported that 113 Covid-19 patients were treated with IVIG. Patients who received IVIG had a longer hospital stay of 23.0 days (19.0–31.0) with a higher mortality rate than the control group (9 (19.1%) vs 4 (6.1%), p= 0.032) [30]. Hou et al. stated that IVIG improved neither in-hospital mortality nor the need for mechanical ventilation in severe Covid-19 patients. Liu et al. stated that they treated 421 severe Covid-19 patients with IVIG and they observed no significant differences in 28-day mortality, acute respiratory distress syndrome, acute hepatic injury, acute kidney injury, diffuse intravascular coagulation, myocardial injury, shock and invasive mechanical ventilation between the IVIG and control group [31]. Focosi et al. evaluated 2401 Covid-19 patients from 10 studies and concluded that IVIG was not associated with reduced death risk, thus the current evidence from the medical literature did not support IVIG therapy in Covid-19 patients [32]. In a recently published retrospective, multi-center cohort study of critically ill Covid-19 patients, 109 patients treated with standard therapy and 74 patients who received IVIG therapy were compared [33]. Salehi et al. reported that there was no difference in length of stay in the ICU, duration of mechanical ventilation, and mortality between standard therapy and IVIG therapy groups. Thus, Salehi et al. concluded that IVIG therapy was not beneficial in critically ill Covid-19 patients [33].

Within our study, there was no statistically significant difference in mechanical ventilation duration and length of stay in the ICU between critically ill Covid-19 patients who survived or died (p=0.32 and p=0.42, respectively). However, we did not have the opportunity to compare critically ill Covid-19 patients who received IVIG therapy plus standard treatment and only standard treatment.

Moreover, the effect of IVIG on mild Covid-19 cases requires further research. Huang et al. reported that 45 non-severe Covid-19 patients who were treated with IVIG had no benefit beyond standard therapy in terms of duration of fever, virus clearance time, length of hospital stay, and use of antibiotics [14].

In this study, laboratory parameters before and after IVIG treatment were evaluated. There was neither a statistically significant increase nor decrease in acute phase reactants such as CRP, procalcitonin, ferritin, and fibrinogen before and after IVIG therapy (p=0.76, p=0.10, p=0.38, and p=0.22, respectively.) The only laboratory parameter which had a statistically significant decrease after IVIG therapy was ALT in critically ill Covid-19 patients (p=0.01) (Table 2).

IVIG may slightly increase liver function tests. However, Chen et al. reported that IVIG was effective in alleviating hepatic ischemia-reperfusion injury in a rat model by reducing ALT, AST, IL-6, and TNF-alpha [34]. Moreover, Omma et al. reported improvement in liver function tests including ALT after IVIG treatment [3].

IVIG treatment is an expensive therapy option in developing countries. Therefore, we had to administer IVIG as a salvage therapy only to severe Covid-19 patients. Unfortunately, 16 (66.7%) of 24 severe Covid-19 patients passed away despite IVIG treatment.

IVIG therapy has the risk of several side effects such as thromboembolism, renal failure, meningoencephalitis, and anaphylaxis [35]. We have encountered no side effects during IVIG therapy in our ICU.

The main limitation of this retrospective study was the small sample size. A larger sample size will help to learn more about the positive and negative effects of IVIG therapy in Covid-19 patients. As our intensive care unit was reserved for only severe Covid-19 patients during the pandemic, this study lacked a control group. The effect of IVIG on severe Covid-19 cases requires further well-designed prospective randomized controlled studies.

CONCLUSION

IVIG treatment was effective in Covid-19 patients with Guillain-Barré syndrome. However, IVIG treatment did not have a statistically significant effect on pre and post-treatment laboratory values, morbidity, and mortality of severe Covid-19 patients in the ICU.

Abstract: *Hippo signaling has been recognized as a newly identified tumor suppressor signaling pathway that can regulate cellular processes including regeneration, cell death, differentiation, and development. Its dysregulation through overexpression of YAP (Yes-associated protein) and TAZ (PDZ-binding motif) as two main oncogenic factors of the Hippo pathway has a crucial role in several cancers. Because of the limited prognosis and therapeutic targets, further understanding of molecular pathways involved in tumorigenesis is one of the interesting issues in studies. Here, we demonstrated that some viruses, through dysregulation of the Hippo signaling pathway can be implicated in transformation, metastasis, and chemotherapeutic drug resistance in virus-related cancer and also help processes involved in the pathogenesis of viral infection such as persistence.*

Keywords: *Hippo signaling pathway, virus, cancer*

INTRODUCTION

The Hippo signaling pathway was discovered to be involved in controlling organ size and cell differentiation in Drosophila melanogaster for the first time, and it has recently been recognized as a critical tumor-suppressor network [1]. Consequently, the correlation of deregulated Hippo pathway signaling in several cancer types such as breast, liver, lung, prostate, gastric and colorectal tumors has been reported. In addition to this role, the Hippo pathway is involved in the conservation of tissue-specific stem cells, tissue renewal, and damage recovery [2,3].

The Hippo pathway is a kinase cascade that includes kinases MST1 and MST2 (also known as STK4 and STK3), large tumor suppressors 1 and 2 (LATS1 and LATS2) and adaptor proteins SAV1 (Salvador homolog 1), and MOB kinase activator 1A and 1B (MOB1A and MOB1B). MST1 and MST2 induce LATS1 and LATS2 phosphorylation, which in turn facilitates LATS-dependent phosphorylation of the homologous oncoproteins YAP (Yes-associated protein; encoded by YAP1) and TAZ (PDZ-binding motif, also known as WWTR1) that inhibit the activation of transcriptional co-activators Yorkie (Yki), YAP, and TAZ [4-6].

Hippo pathway main effectors YAP and TAZ, phosphorylation by the Hippo core complex can retain them in the cytoplasm where they expose to proteasomal degradation [7]. Since TAZ/YAP mutations rarely happen other mechanisms are more likely responsible for Hippo's relevance in cancer. Growing evidence suggests that a complex network of interactions with critical pathways can modulate YAP/TAZ activity such as TGFB, GPCR, Notch, EGFR, and angiogenesis [8].

In the case of modulation of Hippo signaling, stimulation of G protein-coupled receptors (GPCRs) associated with Gas might lead to phosphorylation of LATS and consequently down-regulation of YAP. GPCRs as integral membrane receptors activated by external ligands their binding leads to the activation of the alpha-subunits of subclasses of G proteins. In contrast, stimulation of Ga12/13-coupled GPCRs is associated with suppression of LATS and up-regulation of YAP [9,10].

Other instances of membrane receptors that reported to modulate YAP expression are the receptor tyrosine kinases EGFR and ERBB4 [11]. The EGFR ligand amphiregulin (AREG) is an important YAP target that provides a positive cycle that mediates YAP and EGFR signaling and can stimulate intensifying proliferative signals from both pathways. Also, ERBB4 as a member of the EGFR family, via interaction of YAP and possibly TEAD1 with its intracellular domain in the nucleus, demonstrated either induction of YAP activation or increase expression of YAP target genes [12].

Oncoviruses are associated with about 12% of all human cancers. People carry at least one of these oncoviruses in their life, but these infections only a small proportion of these individuals go on to develop cancer [13]. The interaction between viral factors and the host is a complex process to provide a desirable microenvironment for oncogenesis [14]. The aim of this review is the improvement of our understanding of mechanisms of oncogenesis modulation by different viruses and a better understanding of tumorigenesis that may result in more effective targeted therapy in the future. By the recent rises in viral-related carcinomas and the link between Hippo and viruses, we assessed to determine if Hippo signaling is the main target in such cancers.

HEPATITIS B Virus

In recent decades human hepatocellular carcinoma (HCC) with approximately 746,000 deaths per year, identified as the sixth most common cancer and the third leading reason for cancer-related deaths in human populations [15].

Hepatocarcinogenesis, due to several genetic and epigenetic changes which occur through different stages of the disease is known as a complex process [16]. As regards the fact that hepatitis B virus (HBV) infection has a key role in the establishment of HCC, it is important to know its proteins' roles in Hepatocarcinogenesis. HBV encoded four proteins and among these proteins, the HBV X protein (HBx) is a multifunctional protein and has a critical role in hepatocellular carcinogenesis. Multiple signaling pathways are participating in the HCC progression [17,18].

Many studies are designed to assess the molecular and cellular mechanism of HCC because finding a suitable treatment for HCC is an immediate task for healing patients suffering from HCC. Recently, numerous researches have shown the role of the Hippo pathway in organ size control, cell proliferation, cell death, and tumor progression [19,20]. Although the role of YAP, which is a downstream factor of the Hippo signaling pathway in HCC, remains unclear, this review provides a vision for the regulation of YAP upstream and downstream effectors involved in hepatic cancer [21].

Interestingly, the hyperexpression of YAP can result in epithelial-to-mesenchymal transition (EMT) and may inhibit apoptosis, growth factor-independent proliferation, and anchorage-independent growth [22]. The liver has an amazing characterization that can lead to having unique features such as Growth control which in the liver has some unusual features. The liver has been known for its noticeable capacity to renew consequently to a two-third partial hepatectomy (PHx) or injury. The natural liver in an adult is composed of two parenchymal cell types — hepatocytes and cholangiocytes [23].

Dedifferentiated hepatocytes as multipotent stem cells are capable to be the source of tissue renovation in the damaged liver [24]. Factors of the Hippo signaling pathway including MST1 and MST2 have been demonstrated to have key roles in adjusting or restricting liver progenitor cells. Thus, it is predicted that the Hippo can be involved in the suppression of stem/progenitor cell proliferation in the mature liver [25]. Furthermore, some studies also showed that knocking out YAP resulted in hepatocyte and cholangiocyte injury and loss [26].

In synergy with the functional roles of Hippo signaling, any change of upstream effectors of the hippo pathway like Mst1/2 can result in over-proliferation and sometimes Hepatocarcinogenesis. Since HBV is commonly the major reason for HCC; YAP possibly has an important role in its carcinogenesis. Interestingly, YAP expression is frequently shown to be increased in HBV infections resulting in HCC, infected cell lines, and HBx transgenic mice. Through the CRE-dependent HBx attaching to the YAP promoter, HBx can increase YAP and follow stimulate YAP target genes which leads to the proliferation of hepatoma cells. Findings revealed the importance of the Hippo signaling pathway in cancer and suggested new treatments for HBV-infected patients to inhibit progression to HCC [27].

Studies have revealed that the loss of Mst1/2 may result in the promotion of several tumors in the liver of mice. The loss of both Mst1/2 is required to affect the liver since the loss of Mst1 or Mst2 is not effective on liver size or the number of liver tumors [28]. These findings firmly revealed the effect of Mst1/2 on YAP activity. Interestingly, lack of YAP phosphorylation and impairment of Mst1/2 activity that occurs in carcinogenesis have been reported in 30% of HCCs [29].

The liver-specific NF2/merlin inactivation may lead to an increase in hepatic stem cell number with a lack of any changes in differentiated hepatocytes [30]. The studies on Sav or Mst1/2 positive livers for assessment of the effectiveness of

YAP/TAZ and Lats1/2 phosphorylation in the hippo pathway displayed complex results regarding the need for Mst1/2 or Sav in Lats1/2 phosphorylation [29,31] and since in mouse fibroblasts, for YAP phosphorylation, presence of Mst1/2 was not crucial, it is considered that the pathway may be specific in hepatitis [29].

In a study on transgenic mice, it was shown that YAP induction can lead to abnormal hepatocyte expansion after 2 months and consequently several nodes have been reported in hepatitis [32]. The nodes were reported to be a collection of hepatocytes in a generative condition that condensed the near parenchyma and revealed severe HCC. Also, this liver-specific loss of either Mst1/2 in hepatocytes leads to noticeable liver growth because of its deregulated cell proliferation [28].

On the other hand, when transgenic mice models with YAP hyperactivity crossed with mice lost its DNA-binding domain TEAD2 do not promote HCC. Lacking YAP overexpression may lead to having mice with livers deficiency in Nf2/merlin after crossing with mice that have the defective TEAD2 gene, confirming the therapeutic concept of using the TEAD with YAP in the complex. Verteporfin injection has been demonstrated to reduce liver mass in YAP transgenic animal models and also has no side effect on the wild mice tissue homeostasis, defining the potency of compounds for therapeutic administration in patients with HCC. Verteporfin displayed numerous important features that make its clinical execution for HCC promising [32].

In HCC cell lines induction of YAP results in further resistance to doxorubicin-induced apoptosis; while, inhibition of YAP expression by RNA interference has been reported to reverse YAP-increased chemoresistance. These processes are mediated by the MAP kinase signaling pathway induction rather than an AKT-dependent mechanism of chemoresistance [33]. This process of chemoresistance occurs after treatment by the MEK1/2 suppressor U0126 before doxorubicin injection, which noticeably reduces cell vitality in YAP overexpressing HCC lines [34].

Survivin is accepted as an antiapoptotic protein and in HCC patients identified to be associated with a weak prognosis. Recent studies have shown YAP overexpression is in associate with survivin induction in patients with HCC. It seems that YAP has this oncogenic capacity on the cell with a survivin increase leading to carcinogenesis [35].

HUMAN PAPILLOMAVIRUS

Cervical cancer considers the most important cancer in women because it is the fourth leading reason of cancer-related death in women. Due to the detection of human papillomavirus (HPV) DNA in the majority of cervical cancer patients, high-risk HPV types recognize as the cause of cervical cancer [2].

In a study by Chunbo He et al results implicated that YAP1, one of the main oncogenic effectors of the Hippo pathway, was (11%) amplified several times, whereas LATS1/2, MST1, and FATs, that identified as upstream tumor inhibitors of the Hippo pathway, were not detectable or mutated in cervical cancer patients. YAP1 induction in cervical cancer cells noticeably triggers the expression of EGFR and its related ligands AREG and TGFa. On the other hand, TGFa and AREG, through EGFR signaling, can block the Hippo pathway and induce YAP protein (dephosphorylated LATS1, MOB1, and YAP1) to promote cervical cancer cell growth. Recognition of this circumstance between Hippo/YAP and EGFR in human cervical cancer provides an opportunity to combine targeting of the Hippo/YAP and EGFR pathways to have an efficient way to treat cervical cancer [36].

In addition, hyperactivation of YAP1 can be an important mediator to the persistence of HPV infection. First, studies report that hyperactivated YAP1 increases the expression of HPV receptor molecules such as ITGRA6, SDC1, and EGFR, which through the early stage of HPV infection can help the HPV entry process. Second, is that hyperactivation of YAP1 in cervical epithelial cells may reduce viral pattern recognition by the innate immune system. Some studies report that TLR2 and TLR4 and adaptor proteins MYD88 and TRIF were suppressed, which could facilitate HPV infection. Third, there is evidence that ectopic expression of YAP may suppress the activation of transcriptional factors that are essential for the production of type I IFNs, including IRF1, IRF3, and IRF7, leading to the reduction of IFNA1, IFNB1, and IFNE in hers. IFNs can activate antiviral factors of the immune system and play their role in the progress of innate and adaptive immune responses. Also, some studies showed that the expression and activation of main components of the type I IFN pathway, like IFNAR2, STAT1, JAK1, and IRF9, are suppressed by the expression of YAPS127A in the epithelium of the cervix. Suppression of the IFNAR2/JAK1/STAT1 signaling pathway leads to decreasing of antiviral ISGs, such as MX1, CH25H, and IFITMs (blockers of virus entry), and APOBEC3G, OAS1, ISG15, and IFI44L (suppressors of virus translation and replication) [37].

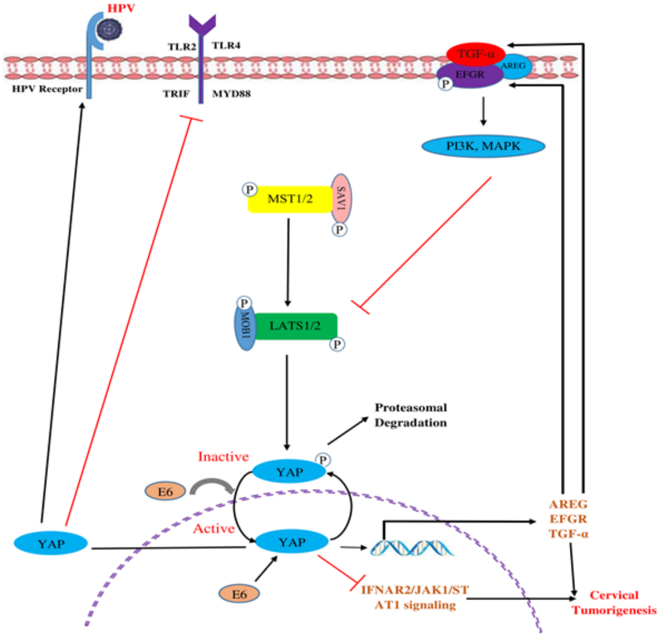
The HPV oncoproteins E6 and E7 expression can result in the suppression of some essential tumor inhibitors such as TP53 and RB1 in many types of cells [38,39]. Suppression of TP53 and RB1 extends cell life (by inhibition of death) and may lead to immortality in cervical epithelial cells, facilitating malignancy of HPV-infected cells by an oncogenic signal (including hyperactivation of YAP1) [40,41].

In epithelial cell cultures, cell-cell contact development is a key step in differentiation before the formation of distinguished apicobasal surfaces. The transcriptional co-activator YAP plays a key role in this event [42,43]. Numerous reports have shown that cell-cell contacts activate the LATS1/2 serine/threonine kinases which can phosphorylate YAP [44,45]. During phosphorylation, YAP restricts from the nucleus and it inhibits the transcription of key genes in the cell cycle [42,46]. A cervical cancer study recently demonstrated that in high-grade cervical lesions levels of nuclear YAP are increased [47].

There are some studies demonstrating that HPV16-E6 or HPV16-E6/E7 double-transgenic mice treated with estrogen may promote cervical cancer [48,49]. Related to that result, other studies report that YAP was increased in the E6 and E6/E7-induced cervical tumor cells, and YAP was localized in the nucleus of these cells [36]. The human foreskin keratinocyte(HFK) “raft” culture infected with HPV16 makes a unique model for the assessment of the HPV16 proliferation cycle [48,50].

YAP can be inactivated by two mechanisms: first, the Ser127 phosphorylation-mediated spatial adjustment (system of nuclear-cytoplasmic shuttling); and second, the Ser397 (Ser381 in YAP protein isoform 2) phosphorylation-mediated adjustment (the phosphodegron-induced degradation). These two mechanisms are applicable directly to prevent YAP oncogenic activity [51,52]. It has been observed that CK1d/ε and SOCS6 proteins are crucial for YAP degradation [52,53]. Although expression of HPV E6 in HT3 cells causes a noticeable increase in CK1d/ε and a reduction in p-YAP (S397), it suggests that the CK1d/ε pathway may not participate in the HPV E6-mediated YAP protein turning [40]. HPV E6 increases YAP protein levels, but also it upregulates the expression and activation of AREG protein in the cell culture. These observations showed a possibility that HPV E6 protein may be associated with the Hippo-ERBB signaling circle and also implicating the transformation and development of cervical cancer. Interestingly, HPV16 E6 and E7 could transcriptionally activate EGFR expression [40,54]. The HPV16 E6 makes receptor protein tyrosine kinase to signaling and facilitates the internalization of phosphorylated receptors [55] (Figure 1).

Figure 1: Schematic presentation of reciprocal interactions between HPV and Hippo signaling pathway



POLYOMAVIRUSES

Through identification of SV40 tumorigenesis in specific laboratory animals and transforms several types of cultured cells offered an opportunity to discover the molecular basis of the tumor. Viral oncogenes were introduced as key tools in the recognition of tumor inhibitor pathways in human primary cells. The p53 and p16/pRb tumor inhibitor pathways have been introduced as targets of SV40 large T. Hahn’s study indicates a transformation model [56], expressed HRas V12, and a construct encoding SV40 large T to target the p14ARF/p53 and p16INK4A/pRb pathways. Recently it is discovered that SV40 small T (ST) (encoded in the large T construct) is needed without requiring large T to enhance anchorage-independent growth [57].

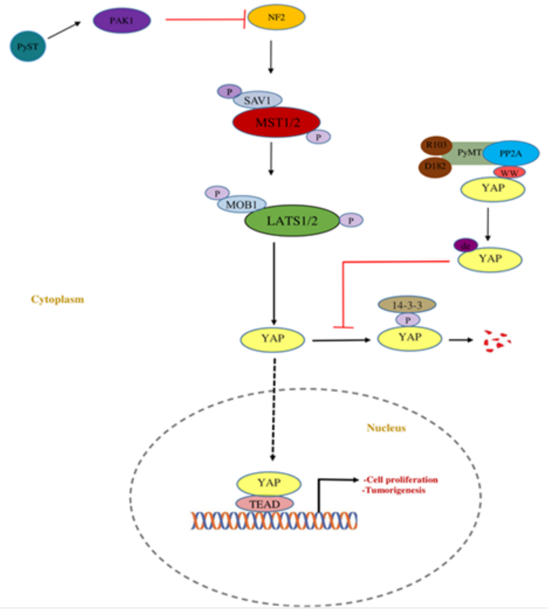
Murine polyomavirus also has frequently presented visions into tumorigenesis by demonstrating important modulation mechanisms including tyrosine phosphorylation and phosphoinositide 3-kinase (PI3K) signaling. Previous studies showed that polyomavirus small T antigen (ST) associates with YAP, an effector of the Hippo pathway, to modulate differentiation. Other studies introduced YAP as a target of middle T antigen (MT) required for transformation [58,59]. Wild-type MT via a surface containing residues R103 and D182 binds to the YAP WW domains. Mutation in each one of R103 or D182 of MT disrupts YAP binding. This happens without disturbing bindings to other signaling factors or the strength of PI3K or Ras signaling. One of the other genetic disruptions of MT binding to YAP or stopping of YAP via short hairpin RNA (shRNA) decreased MT transformation, offering that YAP has an important participation in the transformed phenotype. MT targets YAP via triggering signaling pathways that affect it and consequently bind to it. The signaling of either wild-type MT or the YAP associate MT mutant develops YAP phosphorylation at S127 and S381/397 (YAP2/YAP1) [58]. In addition to previous roles of these phosphorylated serines, MT signaling results in the reduction of YAP from the nucleus and degradation. When MT Binds to YAP, it associates YAP with protein phosphatase 2A (PP2A), resulting in the YAP dephosphorylation together with the MT complex. Furthermore, this process results in the increase of YAP in membranes. Overall, these data demonstrate that YAP develops MT transformation by mechanisms that may be due to YAP's established major transcriptional activation functions [60].

The capability of ST to discuss anchorage-independent growth brings with it its ability to inactivate the PP2A function. Suppression of PP2A may bypass the need for ST in cellular transformation models, and mutations inactivating PP2A subunits have been recognized in tumors [61,62]. PP2A has several substrates including, AKT, b-catenin, and c-Myc which are defined to be activated by ST. Although the total overexpression of these proteins only incompletely replaced ST in cellular transformation, it suggests that undefined PP2A effector pathways may be involved [62].

Hippo/MST kinase acts by a membrane-associated complex including the tumor inhibitor NF2/Merlin [63]. MST kinases enhance activating LATS kinases, which subsequently phosphorylation of the transcriptional coactivators YAP and TAZ, resulting in their inactivation of them via cytoplasmic isolation and increased degradation [64-66]. Suppression of YAP and TAZ restricts proliferation and triggers apoptosis [67].

Interestingly, it is observed that overexpression of YAP is enough to result in tumorigenesis in mice. Both SV40 ST and the Merkel cell polyomavirus ST induce endogenous YAP. Some studies provide data that ST acts through PAK1 to inactivate the NF2 tumor suppressor to alleviate the inactivation of YAP. Activation of PAK1 at the cell membrane is sufficient to bypass the requirement for ST. Restricting PAK1 activity disrupts the transforming capability of the ST protein. Therefore, ST detaches YAP from modulation via the Hippo tumor inhibitor pathway. Induction of Active YAP is required and enough to replace ST in cellular transformation. Therefore, the YAP proto-oncogene is an important mediator of the transforming properties of the ST oncoproteins [68] (Figure 2).

Figure 2: Schematic presentation of reciprocal interactions between Polyomaviruses and Hippo signaling pathway



EPSTEIN-BARR VIRUS

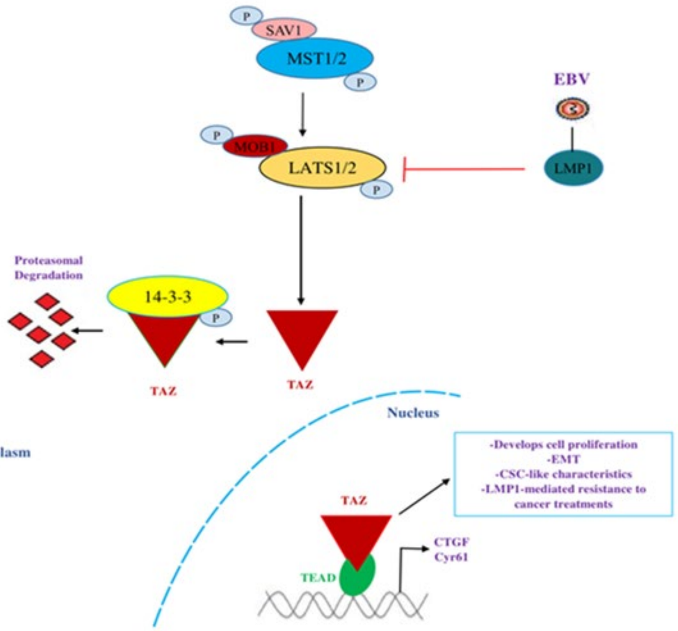
Epstein-Barr virus (EBV) is recognized as a linear dsDNA virus and a member of the human gamma-herpesvirus family that observed to correlate with various B-cell lymphomas, such as Burkitt's lymphoma, Hodgkin's lymphoma, and other tumors like nasopharyngeal carcinoma, T-cell non-Hodgkin lymphomas, and gastric carcinomas. These cancers are firmly correlated with latent Epstein-Barr virus (EBV) infection, genetic factors, and environmental factors thus EBV can regulate mechanisms affecting carcinogenesis, proliferation, death, migration of cells, epigenetic changes in lymphocyte-specific development, and induce cell immortalization. The main mechanisms related to the carcinogenic effectors of EBV consist of LMP1, LMP2, and microRNA that we will introduce bellow [69-71].

The capacity of LMP1 to immortalize and transform cells possibly depends on simultaneously regulating cellular signaling pathways which suppress apoptosis or mediate proliferative, growth factor-like effects. Furthermore, LMP1 can induce a cancer progenitor cells (CPC)-like appearance in epithelial cells, offering that LMP1-induced phenotypic alterations can be related to the promotion of cancer [72]. Therefore, the mechanism and role of LMP1 in immortalizing and transforming cells is complex and several important questions remain to be answered.

Previous studies demonstrated that LMP1 could induce actin remodeling [73]. The actin cytoskeleton is a key factor for the modulation of the Hippo pathway. These data make us investigate How LMP1 can upregulate TAZ expression by inhibition of the Hippo pathway. In a study, findings determined that the LMP1-targeted CNE1-LMP1 cells decreased TAZ expression. The target genes of TAZ are CTGF and Cyr61. Other researches demonstrate that LMP1 can trigger the mRNA expression of CTGF and Cyr61 [74]. There is the possibility that TAZ may be involved in the positive modulation of cell proliferation and survival associated with the obtaining of cancer stem cell (CSC) properties and epithelial-to-mesenchymal transition (EMT) [75, 76]. Previously, some studies have been done to determine if LMP1 can develop EMT by TAZ and define if the morphology alters. The result of these studies has shown some morphological variations from epithelial to mesenchymal phenotypes. LMP1 can develop cell proliferation, EMT, and CSC-like characteristics by TAZ and give us some visions and rationales for the LMP1-mediated resistance to cancer treatments [74].

On the other hand, it has been shown that phosphorylation of the WW domain of the transactivator TAZ by activated LATS1/2, leads to TAZ degradation [77]. Studies have shown that LMP1 can elevate the level of TAZ and increase TAZ nucleus translocation. Thus, it is possible that LMP1 could suppress LATS1/2 activation, resulting in the enhancement of TAZ stability [74] (Figure 3).

Figure 3: Schematic presentation of reciprocal interactions between EBV and Hippo signaling pathway



KAPOSI'S SARCOMA-ASSOCIATED HERPESVIRUS

Kaposi sarcoma-associated herpesvirus (KSHV) is a double-stranded linear DNA virus of the human gamma-herpesvirus family from rhadinovirals and also an oncogenic virus that is responsible for human Kaposi sarcoma (KS) and is associated with an AIDS-defining malignancy. One of the main viral proteins of KSHV is a viral G-protein-coupled receptor (vGPCR). KSHV encodes vGPCR which is essential for the initiation and progression of Kaposi sarcoma [78-80]. Previous studies identified that YAP/TAZ, two homologous oncoproteins that can be suppressed by the Hippo tumor inhibitor pathway, activates in KSHV-infected cells in in vitro conditions, KS-like tumors in mice, and clinical human KS samples [81].

The molecular process to which vGPCR contributes in KSHV-induced oncogenesis remained uncertain but it is suggested to be involving both direct and paracrine oncogenic effects, that are activated by growth factors including VEGF and PDGF induced by vGPCR [82,83]. The KSHV protein (vGPCR) activity is via Gq/11 and G12/13 to suppress the Hippo pathway kinases Lats1/2, enhancing the activation of YAP/TAZ. Also, clearance of YAP/TAZ inhibits vGPCR-induced cell proliferation and tumorigenesis in a xenograft mice model. The transformation of cells mediated by vGPCR is sensitive to pharmacological blockers of YAP [84,85].

It is demonstrated that the Knockdown of YAP or TAZ can inhibit the vGPCR-induced CTGF expression, offering that YAP/TAZ enhances the biological functions of vGPCR. In addition to the Hippo pathway, studies have shown other signaling pathways that have also been related to the oncogenic effect of vGPCR [85]. For instance, PI3Kγ is activated by vGPCR and has a key role in vGPCR-induced sarcomas, whereas NFkB has an indirect role in vGPCR-induced paracrine neoplasia. It seems the activation of YAP/TAZ is associated with other vGPCR downstream signaling events, including PI3K and NFkB, which generally participates in KS tumorigenesis in KSHV-infected patients. It is noticeable that YAP/TAZ also upregulates the expression of several growth factors, including CTGF and insulin-like growth factor (IGF) [86,87], that can be associated with neoplasia caused by vGPCR in a paracrine condition [81, 88].

Some studies revealed that Hippo pathway activation has a key role in the promotion of the lytic cycle and transition from latency. Inactivation of the Hippo pathway modulator YAP1 may promote reactivation from latency, lytic protein increase, and production of infectious virions. Interestingly, expression of the YAP1-inactivating kinase LATS1 consequently induces reactivation from latency. Conversely, LATS1 silencing decreases viral protein expression along the late phase of lytic replication. However the detailed mechanism of switching of KSHV latent/lytic by the Hippo signaling pathway is still unclear, increased amounts of nuclear centers containing the viral latency-associated nuclear antigen (LANA) have been reported in YAP1-silenced cells [89] (Figure 4).

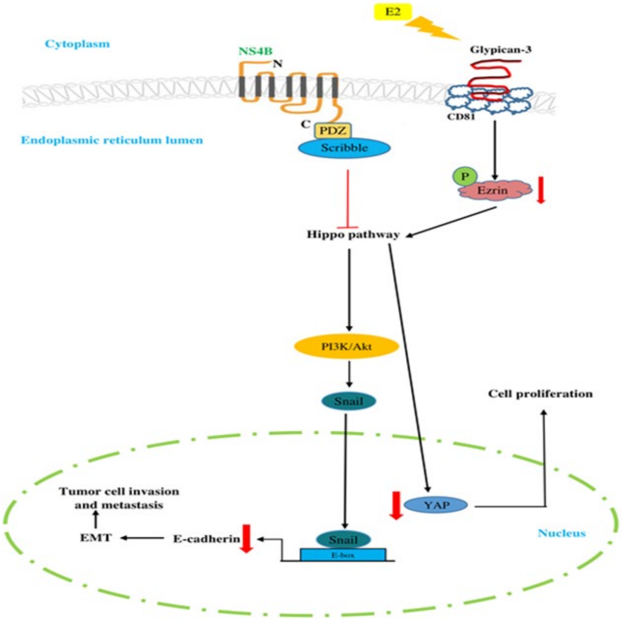
HEPATITIS C VIRUS

Hepatitis C virus (HCV), a member of the Flaviviridae family, is an enveloped RNA virus with a positive sense single-strand RNA genome [90]. Chronic HCV infection is one of the main risk factors for disease progression to metabolic disorders, fibrosis, cirrhosis, and HCC [91]. Epithelial-to-mesenchymal transition (EMT) is a physiological process by which epithelial cells lose their cell polarity and cell-to-cell junctions, and achieve migratory and invasive properties to become mesenchymal cells [92]. Previous literature reviews have shown that EMT plays a crucial role in promoting metastasis in various human cancers including HCC [93]. During the process of EMT, loss of epithelial markers, especially E-cadherin is mediated by transcriptional repressor SNAIL that binds to the E-box motif on the promoter region of E-cadherin [94]. HCV non-structural 4B (NS4B) protein is a 27kDa hydrophobic protein that role in HCC pathogenesis mediate interaction networks with cellular host proteins [95]. A study recently showed that interaction NS4B with scribble protein, a scaffold protein involved in regulating cell polarity and cell proliferation in epithelial cells, suppresses the Hippo signal pathway that subsequently results in the induction of the PI3K/AKT pathway. Induction of the PI3K-Akt pathway upregulates Snail expression via translocation to the nucleus. Finally, the up-regulation of Snail induces EMT progression by reducing E-cadherin expression which contributes to HCV-caused HCC progression, invasion, and metastasis [96].

HCVs entry to hepatocytes is recognized to be mediated by CD81 [97]. Ezrin is a member of a membrane-cytoskeleton linking protein that increases in HCC and is identified in correlation with malignant HCC [98]. In normal hepatocytes, CD81 overexpression results in the phosphorylation of ezrin and increasing nuclear YAP. As the CD81-SYK-ezrin complex causes signals to modify cell construction through protein interactions, gene expression is mediated by YAP via downstream regulation of the Hippo signaling pathway [99]. Also deregulation of the Hippo signaling pathway and increased YAP activity have been demonstrated in 50% of HCC cases [100]. In contrast since Glypican (GPC)-3 is one of the main ligands for CD81, it upregulates the expression of CD81 in HCC cells enhances activation of Hippo, a reduction in ezrin phosphorylation, and a reduction in YAP. Interestingly HCV E2 protein mimics the function of GPC3, enhances the activation of the Hippo signaling pathway, and subsequently reduces YAP and cell proliferation. Consequently, although any hepatocytes which have missing CD81 expression are considered to be resistant to HCV infection but can expand faster than the normal hepatocytes, loss of CD81 is a usual event in the promotion of hepatic neoplasia [101] (Figure 5).

Figure 5: Schematic presentation of reciprocal interactions between HCV and Hippo signaling pathway



CONCLUSION

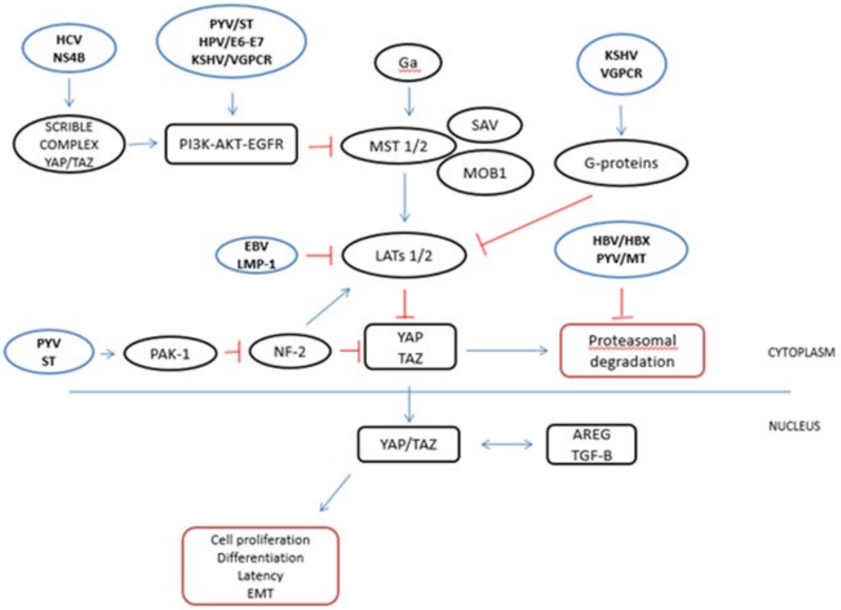
The Hippo signaling is an emerged evolutionarily conserved tumor suppressor pathway that regulates proliferation, apoptosis, differentiation, and development, whose dysregulation overexpresses YAP and TAZ as two major oncogenic downstream effectors of Hippo pathways that play a crucial role in multiple human pathological diseases, such as cancer (Table 1).

Table 1: The summary of the deregulation of the hippo signaling pathway by oncoviruses

Virus	Viral protein	Component of hippo signaling	Mechanism/Effect	References
HBV	HBx	YAP	HBx can increases YAP via the CRE-dependent HBx binding to the YAP promoter and following stimulation of YAP target genes	[27]
HPV	-	YAP1	Hyperactivation of YAP1 can be an important mediator in the persistence of HPV infection	[37]
	-	YAP1	Hyperactivation YAP1 increases the expression of HPV receptor molecules such as ITGRA6, SDC1, and EGFR	[37]
	-	YAP1	Hyperactivation of YAP1 in cervical epithelial cells may reduce viral patterns recognition TLR2 and TLR4 and adaptor proteins MYD88 and TRIF of the innate immune system	[37]
	-	YAP1	Expression of YAP may suppress the activation of transcriptional factors that are essential for the production of type I IFNs, including IRF1, IRF3, and IRF	[37]
	E6/E7	YAP	Expression and activation of main components of the type I IFN pathway, like IFNAR2, STAT1, JAK1, and IRF9, suppressed by expression of $YAPS^{127A}$	[37]
		YAP	YAP was increased in the E6 and E6/E7-induced cervical tumor cells and YAP was localized in the nucleus of these cells	[36]
PyVs		ST YAP	Polyomavirus small T antigen (ST) associates with YAP, an effector of the Hippo pathway, to modulate differentiation	[58]
		MT YAP	MT Binds to YAP, it associates YAP with protein phosphatase 2A (PP2A), resulting in the YAP dephosphorylation together with the MT complex	[60]
		ST YAP	ST acts through PAK1 to inactivate the NF2 tumor suppressor to alleviate the inactivation of YAP	[68]
EBV		LMP1 TAZ	LMP1 can upregulate TAZ expression by inhibition of Hippo pathway proteins	[74]
		LMP1 TAZ	LMP1 can develop cell proliferation, EMT, and CSC-like characteristics by TAZ	[74]
		LMP1 LATS1/2	LMP1 could suppress LATS1/2 activation, resulting in the enhancement of TAZ stability	[74]
KSHV		vGPCR Lats1/2	The KSHV protein (vGPCR) activity is via Gq/11 and G12/13 to suppress the Hippo pathway kinases Lats1/2, enhancing the activation of YAP/TAZ	[85]
		vGPCR YAP/TAZ	Activation of YAP/TAZ is associated with other vGPCR downstream signaling events, including PI3K and NF-kB	[86,87]
		- YAP1	Inactivation of the Hippo pathway modulator YAP1 may promote reactivation from latency, lytic protein increasing, and production of infectious virions	[89]
		LATS1	Expression of the YAP1-inactivating kinase LATS1 consequently induces reactivation from latency	[89]
HCV	*NS5B*	-	*Interaction NS4B with scribble protein suppresses the Hippo signal pathway that subsequently resulting in the induction of PI3K/AKT pathway*	[96]
	E2	YAP	HCV E2 protein mimics the function of GPC3, enhances the activation of the Hippo signaling pathway, and subsequently reduces YAP	[101]

The activation of YAP and TAZ contributes to cancer initiation, metastasis, and anticancer drug resistance via interactions with several signaling pathways in many human tumors. Oncoviruses either directly or indirectly by modulating a variety of cellular signaling pathways lead to the dysregulation of the Hippo signaling pathway to increase the expression of the downstream effectors TAZ and YAP which can be implicated in transformation, metastasis, and chemotherapeutic drug resistance in virus-related cancer and also to facilitate some processes involved in the pathogenesis of viral infection such as entry, persistence, escape from the immune system, and latency. However, in some cases inactivation of YAP can aid the pathogenesis of KSHV and HCV. (Figure 6).

Figure 6: Schematic presentation of reciprocal interactions between oncoviruses and Hippo signaling pathway



With these interpretations, we recommend that the overexpression of the major downstream effectors of the Hippo pathway, TAZ, and YAP can be used as prognosis markers in cancers caused by oncoviruses. Overall, Hippo signaling is a new pathway in viral infection, and in this way, better understanding interaction between oncoviruses with Hippo signaling can be used as a new therapeutic target in virus-caused cancers.

Abstract: *Improving the mental health of nurses and investigating the factors affecting it leads to the improvement of job performance and the quality of nursing care. Aim: The present study aimed to determine the relationship between mental health, life satisfaction, and job satisfaction of nurses in Ilam city in 2022. The present correlational study was carried out on 160 nurses working in educational hospitals of Ilam city and was selected by stratified random sampling in 2022. A four-part questionnaire was used: the first part included a question on demographic information. Minnesota Satisfaction Questionnaire (MSQ) (1977), Diener et al.'s Satisfaction with Life Scale (SWLS) (1985), and Derogatis et al.'s Symptom Checklist-90 (SCL-9) (1973) were included in the second, third and the fourth parts, respectively. Results showed no significant relationship between the total score of mental health and the total score of job satisfaction. There was a significant relationship between the total job satisfaction score and life satisfaction score (r=0.267, p=0.001). There was also an inverse and significant relationship between the total mental health score and the life satisfaction score (r=0.294, p=0.001). The collected data was analyzed using descriptive tests (frequency, mean percentage, and standard deviation) and non-parametric Spearman and Kruskal-Walli's correlation tests in SPSS ver. 22. P-value<0.05 was considered as the significance level in all tests. Job satisfaction is effective in creating motivation, efficiency, responsibility, and social accountability in the personnel of any organization. Job dissatisfaction can lead to complications such as job burnout, illness, absenteeism, the job left, leaving many nursing jobs, and the reluctance of the young workforce to attend the wards. Therefore, it is necessary to make further efforts in this field by healthcare policymakers.*

Keywords: *mental health, life satisfaction, job satisfaction*

INTRODUCTION

Mental health has an expanded definition. But every person who can deal with his/her deep issues, get along with him/herself and others, and can face his/her inevitable internal conflicts, and does not isolate him/herself from society, can be stated to have mental health [1-4]. Nurses are directly related to all social strata and touch people's problems closely. This close relationship doubles their serious responsibility toward people's health [5]. Nursing is one of the most stressful professions so the National Institute for Occupational Safety & Health has introduced it among the top 40 stressful professions [6].

There are many sources of occupational stress in the nursing work environment. Overwork, urgency, patient death, independent practice, lack of social support, poor job fit, lack of necessary specialized knowledge, unsafe workplace and rapidly changing healthcare environment are known as nursing stressors [7]. Nurses are prone to health threats in different dimensions due to long work shifts and the resulting fatigue. Nurses with no good general health are not able to provide good care such as physical and psychological support to patients. This increases the risk of mistakes and occupational accidents, and subsequent consequences affect the patient and the nurse [8].

Nurses' stress and fatigue can affect the vital and critical aspects of their performance, including problem-solving ability, decision-making ability, and creativity, and ultimately lead to disruption in medical care. Because patient safetyو health and recovery depend on the safe and optimal performance of nurses [9]. Many researchers have confirmed that job-related stress can have harmful effects on the physical and mental health of individuals [10,11]. Job stress is one of the factors affecting the health of employees. Employees' health is at risk when they face various stressors. This issue is more evident in the nursing profession [12]. The impact of job dissatisfaction on the mental health of employees has been a public concern in various societies, especially in recent years. Perceived impacts of job dissatisfaction on people's mental health from an economic point of view is also an important issue and play an important role in the quality of professional and personal life of nurses [13].

Another variable that plays a key role in improving nurses' mental health is life satisfaction. Life satisfaction is one of the mental health-related factors and refers to a person's general attitude and evaluation toward life as a whole [14]. It also reflects the balance between a person's aspirations and his/ her current situation. The greater this balance, the greater the life satisfaction will be [7]. According to previous studies, this concept is in full interaction with health and there is a close relationship between physical and mental health with life satisfaction [15]. Lyubomirsky believes that people who have higher life satisfaction, use more effective and appropriate coping methods, experience deeper positive emotions and feelings and have higher general health [16]. Nurses are among the vulnerable employees of society, whose health and balance in their personal and family life is related to occupational variables. Work-family conflict causes psychological symptoms such as higher stress, depression, chronic physical problems, increased physical complaints, lower life satisfaction, low quality of family life, and low energy levels [17]. Suzuki et al. stated that nurses were in 27th place in the evaluation of 130 stressful jobs sorted according to their reference to doctors for health problems [18].

Improving the mental health of nurses and investigating the factors affecting it leads to the improvement of job performance and the quality of nursing care. Since nursing is one of the sensitive professions and nurses spend an important part of their lives with people and patients, their mental health leads to optimal job performance and guarantees the health and improvement of many patients and people [19].

Having job satisfaction, life satisfaction and mental health leads to an improvement in the quality of patient care and increasing productivity and improving nursing services, therefore, conducting relevant studies and using their results in various aspects of the nursing profession can have useful results in care, education, management, therapy and also the personal life of a nurse [20]. Therefore, the present study aimed to determine the relationship between mental health, life satisfaction, and job satisfaction of nurses in Ilam city in 2022.

MATERIALS AND METHODS

The present correlational study was carried out on 160 nurses working in educational hospitals of Ilam city and was selected by stratified random sampling in 2022. Inclusion criteria included working in one of the above-mentioned educational hospitals and having informed consent to participate in the study. Failure to complete one of the questionnaires, an incomplete questionnaire, and unwillingness to cooperate were among the exclusion criteria. A four-part questionnaire was used: the first part included a question on demographic information. Minnesota Satisfaction Questionnaire (MSQ) (1977), Diener et al.'s Satisfaction with Life Scale (SWLS) (1985), and Derogatis et al.'s Symptom Checklist-90 (SCL-9) (1973) were included in the second, third and the fourth parts, respectively. Demographic information of nurses included age, gender, years of work experience, marital status, education level, hospital, ward, position, income level, employment status, number of children, and home type.

Minnesota Satisfaction Questionnaire (MSQ) consists of 19 items and 6 subscales of the payment system, type of job, achievement opportunities, organizational atmosphere, leadership style, and physical conditions. MSQ is scored based on a 5-point Likert scale, ranging from "Completely Disagree" (Score 1) to "Completely Agree" (Score 5). To calculate the overall score of the questionnaire, the scores of all the items are added together. Scores 19-38, 38-57, and 38-57 indicate poor, moderate, and very good job satisfaction, respectively. This questionnaire has been used in many types of research in the world [21-26]. Its internal consistency reliability was measured α = 0.87.

Diener et al.'s Satisfaction with Life Scale (SWLS) is a 5-item instrument designed to measure a person's cognitive and overall judgment of life. This instrument is scored based on a 7-point Likert scale ranging from 1 (Completely disagree) to 7 (Completely agree). The overall score of this scale is calculated by summing the answers and the possible score range is 5 and 35. A higher score indicates higher levels of life satisfaction. This questionnaire has also been used in many types of research in the world [27-32]. The Cronbach's α reliability was 0.86.

Derogatis et al.'s Symptom Checklist-90 (SCL-9) can be completed within approximately 25 minutes. This questionnaire is the short form of SCL-90 and was extracted by Najarian & Davoudi based on the original form and through exploratory factor analysis. It consists of 25 items and 9 subscales of somatization (6 questions), obsession-compulsion (3 questions), interpersonal sensitivity (3 questions), depression (2 questions), anxiety (3 questions), phobia (3 questions), paranoid thoughts (1 question), psychosis (3 questions), hostility (1 question). SCL was answered according to its original form and based on a 5-point Likert swale ranging from None or Rarely (0), A little (1), To some extent (2), A lot (3), Very much or Strongly (4). The overall score of general psychological injuries was extracted. Higher scores indicate more damage [30]. The Cronbach's alpha reliability of the tool was calculated α = 0.94.

The collected data was analyzed using descriptive tests (frequency, mean percentage, and standard deviation) and non-parametric Spearman and Kruskal-Walli’s correlation tests in SPSS ver. 22. P-value<0.05 was considered as the significance level in all tests.

Ethical considerations: The present study was approved by the Ethics Committee of Ilam University of Medical Sciences with the code IR.MEDILAM.REC.1400.229. The contents of the Nuremberg and Helsinki declarations and the 26 research ethics codes were observed.

RESULTS

The results showed that most of the participants were female (61.2%), aged 26-29 (40%), single (52.5%), childless (75%), owning their own house (72.5%), and had 6-10 million-toman income (70%). Also, the majority of participants had a bachelor's degree (88.8%), less than 6 years of work experience (70%), were ward nurses (91.2%), were permanent nurses (45%), and worked in ICUs (45%).

Table 1 shows the correlation matrix of job satisfaction, life satisfaction, and mental health. This table determines the relationship between job satisfaction, life satisfaction, and mental health of research subjects. The table shows no significant relationship between the total score of mental health and the total score of job satisfaction. There was a significant relationship between the total job satisfaction score and life satisfaction score (r=0.267, p=0.001). There was also an inverse and significant relationship between the total mental health score and the life satisfaction score (r=0.294, p=0.001).

Kruskal-Walli’s test shows the relationship between job satisfaction, life satisfaction, and mental health according to demographic characteristics (Table 2). This table shows that the highest frequency of the variables of work experience, education level, medical training center, hospital ward, income level, and employment status are related to less than 3 years (p=0.017, df=4, k=11.98), BA (p=0.014, df=1, k=6.07), Ayat-Allah-Taleghani hospital (P=0.004, df=2, k=11.03), ICUs (P=0.001, df=2, k=55.91), 6-10 million tomans(P=0.022, df=2, k=7.62), and contractual employment (P=0.001, df=2, k=14.37), which are all had a statistically significant relationship with job satisfaction. The highest frequency of gender, marital status, and employment status were related to females (P=0.037, df=1, k=4.34), married individuals (P=0.034, df=1, k=4.47), and contractual individuals (p=0.032, df=2, k=6.88), which all had a statistically significant relationship with life satisfaction. Also, the female gender (k=11.75, p=0.001, df=1) had a statistically significant relationship with mental health.

DISCUSSION

Mental health affects health-related variables related to [4,33-35]. The results of the present research showed no significant relationship between each of the mental health components and the total score of job satisfaction. There was also no significant relationship between the total scores of job satisfaction and mental health. However, there was an inverse and significant relationship between the two components of job satisfaction and some mental health components, that is between the payment system with physical complaints, interpersonal sensitivity, phobia, and the overall mental health score, and also between the type of job with obsessive-compulsive and paranoid thought.

Kahe et al. revealed a statistically significant relationship between overall job satisfaction with employees' mental health, and people with high job satisfaction obtained a better mental health score (below average) (p=0.02). In other words, the lower the level of mental health, the lower the job satisfaction and vice versa [36].

Table 1: Correlation matrix of job satisfaction, life satisfaction, and mental health (Spearman correlation)

Variable			*Correlation*	
Variable	**Life satisfaction**	**Mental health**	**Meaningful**	
Job Satisfaction	0/267	-0/063	r	*1*

Veysey et al. showed an inverse relationship between the general health questionnaire and job satisfaction and a direct relationship with the increase in cases of stress [37]. In her study in teaching hospitals of Hormozgan, Mastaneh et al. (2013) also showed a significant negative correlation between mental health pay satisfaction (p<0.005) and type of work (P<0.01) [38].

Sarafis et al. also showed a significant relationship between the stress management domain of health-promoting lifestyle and the payment system domain of job satisfaction (p< 0.005) [39].

Ghasemipirbalooti et al. found a statistically significant relationship between mental health and job satisfaction of the employees of Shahrekord University of Medical Sciences (p=0.001) [40].

Mei et al. (2015) investigated the effect of psychological characteristics of employees on their performance and job satisfaction and the indirect effect of feelings on their relationships. They concluded a positive and direct relationship between job satisfaction with psychological characteristics and positive feelings of employees [41].

Many studies have shown a direct relationship between mental health and job satisfaction [42-47].

The results of this study show an inverse and significant relationship between life satisfaction and each of the components of mental health except for the "paranoid thought" component. The results also show that the level of mental health of nurses increases and mental injuries decrease with increasing life satisfaction scores. Salimi also showed in research titled "Investigating mental health and its relationship with job burnout and life satisfaction of employees" that there is a significant relationship between mental health and life satisfaction.

The consistency between the results of the present research with Salimi's study is attributed to the correlation between mental health and life satisfaction. That is, life satisfaction prerequisite for mental health, and if there is no satisfaction, negative mood and despair dominate the person and make him/her susceptible to all kinds of mental illnesses [48].

In a study on nurses in Ahvaz government hospitals, it was found that life satisfaction is correlated with high mental health (Birgani et al.). The higher the level of life satisfaction, the more likely a person is to experience positive emotions and feelings [49]. Geravand also showed in a study that mental health has a direct effect on life satisfaction.

Changes in mental health and emotions can lead to changes in life satisfaction and a person's attitude [50]. The results of various research show a significant relationship between mental health and life satisfaction. The results of Ferguson's study indicated the interaction between mental health and life satisfaction [51].

In a study of the level of job satisfaction of nurses in hospitals affiliated with Kashan University of Medical Sciences and related factors, Tagharobi et al. showed a statistically significant relationship between the level of education, major stress in the last six months, the workplace, the level of life satisfaction, mental health satisfaction health, pay satisfaction, satisfaction with the number of employees in each shift, satisfaction with the feedback of patients and their families, satisfaction with the treatment and performance of doctors, satisfaction with the treatment and performance of head nurses and colleagues, satisfaction with the treatment and performance of nursing office managers, satisfaction with workplace amenities and happiness with job satisfaction [52].

As was pointed out by Grant, nurses are among the most vulnerable working group in society, and their health and personal-family life balance are strongly related to occupational variables. Work and family life conflict and subsequent stress cause psychological symptoms such as higher stress, depression, chronic physical problems, increased physical complaints, lower life satisfaction, low quality of family life, and low energy levels in these people [17].

CONCLUSION

According to the results of the present study, nurses' life satisfaction score increases with the increase in their job satisfaction score. But there is no significant relationship between the total mental health score and the total job satisfaction score. However, there is an inverse and significant relationship between mental health and life satisfaction. On the other hand, the level of mental health of nurses increases, and mental injuries decrease with the increase in life satisfaction scores. Considering the vital role of nurses in achieving the goals of the health system and public health, neglecting the job dissatisfaction of nurses may have consequences such as reducing productivity, reducing the level of responsibility, reducing the level of quality of their performance, reducing life satisfaction and increasing the number of psychological injuries. Job satisfaction is effective in creating motivation, efficiency, responsibility, and social accountability in the personnel of any organization. Job dissatisfaction can lead to complications such as job burnout, illness, absenteeism, the job left, leaving many nursing jobs, and the reluctance of the young workforce to attend the wards. Therefore, it is necessary to make further efforts in this field by healthcare policymakers.

Abstract: *Introduction: Self-care behaviors are very important to control type 2 diabetes. The current study was conducted aiming at determining the effect of the educational intervention based on mobile short message service on the self-care behaviors in patients with type 2 diabetes in Khorram Abad. Methods: This study was a semi-experimental study on 191 patients with type 2 diabetes (45case and 45 controls). Data collection tools included a demographic information form, International Physical Activity Questionnaire, Self-Care Scale, and Self-Efficacy Scale. Three to four educational messages were sent daily through mobile phones as an educational intervention. Data were analyzed with SPSS V24 at a significance level of 0.05. Findings: The data analysis indicated that the average score of self-care, self-efficacy, and blood sugar was significantly higher in the case group than in the control group before and after the intervention (P<0.001). However, in terms of the physical activity variable, this relationship was not statistically significant in the case and control groups. Conclusion: Educational interventions to empower diabetic patients by strengthening their self-care can be an effective way to improve the health of diabetic patients. Therefore, it is suggested to use patient empowerment programs, especially with a self-care approach, to improve the health of patients.*

Keywords: *self-care, self-efficacy, physical activity, blood sugar, type 2 diabetes*

INTRODUCTION

Diabetes is the most common disease caused by metabolic disorders, which is mainly characterized by a chronic increase in blood sugar and disturbed carbohydrate, fat, and protein metabolism. In general, diabetes is a multifactorial disorder diagnosed by a chronic increase in blood sugar or hyperglycemia (according to diagnostic criteria) and is caused by a disorder in insulin secretion or function or both [1]. Retinal damage and blindness, peripheral neuropathy, leg pain, stroke, peripheral vascular problems, end-stage renal disease, and limb amputation are among the most serious complications of diabetes [2]. The most common type of diabetes is type 2 diabetes, which accounts for approximately 90-95% of diabetes cases and is usually associated with metabolic disorders, weight gain, and physical inactivity [3]. About 422 million people worldwide suffer from diabetes, the majority of whom live in low- and middle-income countries, and in 2019, diabetes was introduced as the direct cause of 1.5 million deaths [4]. According to the International Diabetes Federation (IDF), the number of diabetic patients will reach 439 million people in 2030, and the prevalence of diabetes in developing countries will be 69% [5]. More than 3 million people with diabetes live in Iran [6]. By 2030, Iran will be one of the most prevalent regions in the world in terms of diabetes [7]. Paying attention to the chronic and costly nature of this disease for the general health of society and the creation of a large financial burden, it is essential to pay serious attention to this problem and its consequences [8]. According to the results obtained from the studies, the long-term complications of this disease, including neuropathy, nephropathy, and retinopathy can be prevented, or at least the occurrence of these complications can be postponed if blood sugar is controlled [9, 10]. Many studies have found physical activity and exercise to be effective in reducing blood sugar levels and controlling diabetes [11,12]. The World Health Organization considers education to be the basis of diabetes treatment. Therefore, self-care is one of the important topics of diabetes treatment. Self-care is a learned regulation function in humans, which is based on the ability of people to perform care actions on themselves [13]. It includes the behaviors of following a proper diet, taking medicine on time, self-monitoring of blood sugar, performing regular physical activity, and physical care of the feet [14]. Studies show that 67% of patients with type 2 diabetes do not monitor their blood sugar according to the recommendations. Also, only 19-30% of diabetic patients use the recommended physical activities and compliance with nutritional behaviors in these patients is 65%, and only 7% of diabetic patients fully adhere to all aspects of self-care behaviors [15, 16]. Self-efficacy is also known as a strategy to improve self-care in diabetic patients, which results in self-confidence and adherence to care recommendations to control blood sugar in these patients [17].

Nowadays, to follow up and educate diabetic people, new communication systems are required to direct the focus of care and treatment from the clinic to the patient's daily life. Researchers have pointed out the use of mobile phone service as a method of education and follow-up in chronic diseases, that short message is one of the main functions of mobile phone in the education of diabetic patients [18,19].

Considering the importance of self-care in controlling the blood sugar of diabetic patients and the value of self-efficacy as one of the self-care approaches, it seems necessary to design educational interventions on the platform of mobile phones and in the form of short messages as a relatively new educational method in controlling the disease of diabetics. Thus, the present study was conducted to determine the effect of the educational intervention based on mobile phone short messages on self-care in patients with type 2 diabetes referred to the diabetes clinic in Khorramabad.

MATERIALS AND METHODS

The present study was a semi-experimental intervention research with a pre-test and post-test design. The sample size was specified as 90 people who were selected from the research population of patients with type 2 diabetes referring to the diabetes clinic in Khorramabad, Lorestan province. The participants were selected according to the inclusion criteria using random sampling. Then, they were divided into case and control groups using a simple randomization method (45 ones in each group). The inclusion criteria include informed consent to participate in the research, having a minimum level of literacy and understanding of the content sent through text messages, having a fixed personal mobile number to receive educational SMS, lack of any serious diabetic complication, and not having special diets because of specific diseases or physical problems limiting physical activity. Exclusion criteria include suffering from serious complications of diabetes during the study, suffering from diseases that limit physical activity or nutrition, and the patient's unwillingness to receive educational messages.

Data collection tools in this study included a demographic information form, International Physical Activity Questionnaire (IPAQ), a Self-Care Scale developed by Tubert, and Self-Efficacy Scale. Demographic information included: age, height, weight, gender, educational level, employment status, marital status, and type of treatment. The IPAQ with seven items measured the duration of physical activity in the last week in four categories: moderate physical activity, intense physical activity, walking, and sitting activities. According to the scoring protocol in this questionnaire, the intensity of physical activity based on the ratio of energy consumption in terms of metabolic equivalent of task (MET) in the last seven days is classified into three levels: low, medium, and high. It was proposed by the World Health Organization and the Centers for Disease Control and Prevention in 1998 to measure the physical activity of people aged 15 to 69 years and its validity and reliability have been confirmed in 12 countries worldwide, including Iran [20,21]. A self-care questionnaire was used in this study that included 15 items in the areas of diet compliance, physical activity, blood sugar monitoring, insulin injection or diabetes pill consumption, foot care, and smoking, which was translated and standardized by Hamdzadeh [22,23]. The self-efficacy questionnaire, which is one of the constructs of the standard Health Belief Model Questionnaire, validity and reliability of which have been confirmed [24].

After presenting a letter of introduction from the Iran University of Medical Sciences and obtaining the necessary permits, the researcher referred to a diabetes clinic in Khorram Abad and selected 90 people from among 200 eligible people using random sampling. People who were willing to participate in the study and met the inclusion criteria were assigned to the case and control groups (45 in each group) using a simple randomization method. After random allocation, blood sugar samples were taken in all groups four days before the start of the intervention. In the first session, the researcher explained the purpose of the meeting to the participants, and written informed consent was obtained. Then, the personal information form and questionnaires were completed by the case and control groups. The case group received an educational program in the form of short educational messages via mobile phone, for four weeks and on average, at least three to four messages per day related to the educational content, including exercise, self-monitoring of blood sugar, diet, insulin therapy, medication use, and foot care. For example, short messages about physical activity and blood sugar monitoring were "for people with diabetes, walking is the best exercise" or "it is better for people with diabetes to measure their fasting blood sugar after waking up". To improve self-efficacy, encouraging messages about adherence to self-care were used.

Finally, after two months, the same questionnaires (demographic, physical activity, self-care, and self-efficacy scales) were distributed and completed by the participants, and the blood sugar levels of the two groups were measured again. During this period, the control group did not receive any educational intervention.

However, to comply with the ethical principles, an educational CD containing self-care training was given to the control group after completing the research. The data of the two groups before and after the intervention were entered into SPSS version 24 software and analyzed using Wilcoxon, Mann-Whitney, Chi-square test, independent t-test, and paired t-test at a significant level of 0.05.

RESULTS

The participants' average age was 51.01 ± 0.967, and the average height and weight were 164.57 ± 1.031 and 75.69 ± 1.101, respectively.

Before the implementation of the educational program, the case and control groups were matched in terms of demographic variables, including age, height, weight, gender, education, employment status, marital status, and type of treatment, and no statistically significant difference was observed between the two groups (Table 1).

Table 1: Comparison of the absolute and relative frequency distribution of demographic variables in case and control groups

Variable		Case		Control		P value
		No.	%	No.	%	
Gender	Female	31	69	26	57/7	0.796
	Male	14	31	19	42/2	
Employment	Unemployed	5	11	2	4	0.686
	Housewife	26	58	24	53	
	Self-employed	9	20	9	20	
	Public	5	11	10	22	
Education	Illiterate	5	11	4	9	0.479
	Primary school	17	38	10	22	
	Secondary school	9	20	5	11	
	High school	4	9	11	24	
	High school diploma	4	9	10	22	
	Higher education	6	9	5	11	
Marital status	Single	2	4	1	2	0.800
	Divorced	1	2	0	0	
	Widow	9	20	5	11	
	Married	33	73	39	87	
Type of treatment	Insulin	21	47	21	47	0.920
	Oral medication	20	45	22	49	
	Diet	4	9	2	4	
	Exercise	0	0	0	0	

As observed in Table 2, there is no statistically significant difference in terms of the average score of physical activity, self-care, self-efficacy, and blood sugar between the case and control groups before the intervention, while after the intervention, the average scores of these variables, except for physical activity (P=0.8), was significantly higher in the case group compared to the control group (P<0.001). In the control group, before and after the intervention, no significant difference was observed in the average scores of physical activity, self-care, self-efficacy, and blood sugar (P>0.05).

Table 2: Comparison of the average scores of physical activity, self-care, self-efficacy, and blood sugar, before and after the intervention in case and control groups

Scale	Group	Case	Control	p-value
		Mean ± SD	Mean ± SD	
Physical activity	Before intervention	677.5±954.938	307.5±461.75	0.6
	After intervention	903.75±973.125	655±925.625	0.8
	p-value	0.8	0.4	_
Self-care	Before intervention	2.31±0.813	2.38±0.844	0.12
	After intervention	3.38±0.688	2±0.906	0<0001
	p-value	0<001	0.22	_
Self-efficacy	Before intervention	2.7±0.4	2.7±0.3	0.15
	After intervention	3.7±0.7	2.7±0.7	0<0001
	p-value	0<001	0.286	_
Blood sugar	Before intervention	180±80.5	185±51	0.8
	After intervention	170±87.5	180±70.5	0<001
	p-value	0.009	0.491	_

Table 3: Comparison of blood sugar scores before and after the educational intervention in the case group

Method of treatment	Blood sugar level before the intervention	Blood sugar level after the intervention	Level of change
Insulin	227.09	217.92	-9.17
Oral medicine	173.48	170.65	-2.83
Diet	181	180.44	-0.56
Exercise	194	194.5	0.5
Medium	193.89	190.88	-3.02

Table 3 indicates that the blood sugar level in all patients with different treatment methods (insulin, oral medication, diet) in the case group reduced after the educational intervention compared to before intervention, except for the patients who only used exercise to control their blood sugar.

DISCUSSION

The present study was conducted aiming to determine the effect of the educational intervention based on mobile phone short messages on self-care in patients with type 2 diabetes referred to the diabetes clinic in Khorramabad. The research findings suggest that the educational intervention through mobile phone short messages improved self-care in the case group, which is consistent with findings by Abaza et al. [25] and Agbede et al. [26] on the effect of the intervention based on mobile phone short messages in the self-care of diabetic patients and the findings by Yari et al. [27] and Rahnavard et al. [28] concerning SMS-based and self-care education of diabetic patients. Krishna et al. [29] reported that technologies such as mobile phones and text messages, which are currently part of people's daily lives, have the potential to influence self-care and improve people's health. The approach of health education through SMS to promote self-care in diabetic patients is more welcomed than traditional approaches that require reading pamphlets or attending lectures [25,30].

In this study, self-efficacy also there was a significant difference in the case group in terms of self-efficacy after the educational intervention. Katz and Nordwall [31] and Peymani et al. [32] also found that interventions based on mobile phone messages improve self-efficacy and self-care. Similar studies [33,34] regarding the self-care of diabetic patients also indicate a significant difference in the average score of self-efficacy and self-care in the case group compared to the control group after the educational intervention. These studies are consistent with our work in that increasing self-efficacy causes the adoption of self-care behaviors in diabetic patients. Self-efficacy is an important prerequisite for behavior change [35]. An individual with low self-efficacy is less likely to make an effort to perform a new health behavior or to change the behavior he is used to [36]. Researchers believe that self-efficacy has a suitable framework for understanding and predicting and patient's commitment to self-care behavior in the treatment of diabetes [37].

The results of the present study showed that education through mobile phone short messages does not affect increasing physical activity in the case group, which is in line with the findings by Bakhshian et al[38] regarding the effect of education through mobile phone short messages on self-care of patients with type 2 diabetes. It is also in agreement with the findings by Kim et al. [39] on adherence to diabetes control recommendations, while our findings are not consistent with the study of Paul et al. [40] regarding the use of software that can be installed on mobile phones to improve the amount of daily walking in patients with a history of stroke and the study Martha et al.[41] concerning mobile phone SMS intervention on diabetes self-care activities, cardiovascular disease risk awareness, and food choices among type 2 diabetic patients. This discrepancy can be due to the lack of sports facilities and parks in the current study or the addition of chronic diseases to the patients participating in this research, as well as social and cultural factors that prevent people from doing physical activities in public environments. In the present study, since the number of women is more than men, the problem of social and cultural factors could be more marked.

The use of mobile phone messages in the current study showed a significant positive effect on the reduction of blood sugar in the case group after the educational intervention, which is consistent with the findings of similar studies in this field [42,43,44]. In patients suffering from diabetes, education is as valuable as medicine, exercise, and diet, because the treatment will never be effective unless the patient is well aware of the nature of his disease and takes positive steps to deal with it.

CONCLUSION

The results of this study demonstrated that educational interventions based on mobile phone short messages can be effective in enhancing self-care in patients with diabetes. Educational interventions aimed at empowering diabetic patients by strengthening self-care in them can be an effective way to improve the health of patients with diabetes. Therefore, it is recommended to use patient empowerment programs, especially with a self-care approach, to improve the health of patients.

Conflicts of interest and sources of funding

The personal interests of the authors were not related to the results of this research.

The authors declare that they have no competing interests. This study did not receive any grant from funding agencies.

Acknowledgments

This article is derived from a thesis financially supported by the Research Vice-Chancellor of Iran University of Medical Sciences registered as 97-2-75-12463. All the participants in the research, as well as the officials and staff of Iran University of Medical Sciences and Lorestan University of Medical Sciences, and Khorramabad Diabetes Clinic are highly appreciated for their cooperation with the researcher in sampling

Authors' contribution

All authors were responsible for the study. EA, MM, and TD were accountable for the study Conceptualization and led the writing of the paper. BI conducted the Literature review and assisted in writing the paper. MM and OS performed the Statistical analysis, assisted in interpreting the data, and wrote the paper. OS, FSI, and EA assisted with the interpretation of the results and drafting of programmatic Implications. FB and MM were responsible for data collection and coordination of the study. TD co-led the conceptualization, supervised all aspects of writing the paper, and provided extensive comments on the manuscript. All the authors have read and approved the final manuscript.

Ethics approval and consent to participate

This study was approved by the Research Ethics Committee of the Vice President of Research and Technology of Iran University of Medical Sciences with code IR.IUMS.REC.1397.501. Informed consent was obtained from all individual participants included in the study before conducting.

Consent to publish

All participants consented verbally to the publication of the interview data.

Abstract: *Trust in health care professionals is considered as a basis for patients' care. This study aimed to compare the level of patients' trust in physicians and nurses in both general and COVID-19 wards in a reference hospital in Tehran during the pandemic. This was a cross-sectional descriptive study. The study population comprised patients from Baqiyatallah Hospital in 2022. The data collection tool was the scale of patients' trust in nurses and the Wake-Forest physician trust scale. Data analysis was performed using SPSS-26 software. The level of patients' trust in physicians in COVID-19 wards was significantly lower than in Non-COVID-19 wards (P<0.001), but there was no difference between the two groups in the trust of nurses. The lowest level of trust was in the receiving of required information from nurses, which had a lower score compared to other questions in the questionnaire, and the average amount of receiving required information for patients in general wards was significantly lower than that of patients in COVID-19 (P=0.006). Trust in nurses and physicians in both COVID-19 and general wards was optimum. During the COVID-19 pandemic, the medical staff worked tirelessly and despite the difficulties and complications of the pandemic, patients have high trust in physicians and nurses.*

Keywords: *trust; nurses, physicians; COVID-19; coronavirus*

INTRODUCTION

Physicians and nurses, as the main members of the medical staff, take on different roles, considering the physical, psychological, and social needs of patients. They may act as educators, counselors, mentors, informers, advocates, and act as experts. To play such roles, physicians and nurses need to establish a good relationship with their patients [1,2]. Trust forms the basis of the relationship between the physician or nurse [3] and patient and provides the conditions for the physician or nurse and patient to work together for a better care plan [4]. The relationship between trust and health outcomes is different in individual studies [5]. For example, in a sample of patients with diabetes, trust in a healthcare professional was positively associated with objective and mental health outcomes (glycemic control, health-related quality of life, and patient satisfaction] [6].

The hypothetical relationship between trust and health outcomes is also reinforced by the ethical claims derived from trustworthy and patient-centered relationships in clinical settings [7]. Studies show that patients who have more trust in their therapist are more satisfied with the care and are more likely to follow treatment recommendations [8,9]. Patients' experiences of trust in nursing depend on nurses' knowledge, and the commitment to conversation to build and develop relationships [10]. Therapeutic staff must receive appropriate training to build a bond of trust between themselves and the patient to establish a trustable relationship between themselves and the patient [11]. Trust between patient and therapist is essential to reduce patients' anxiety and build the capacity to control them [12]. The COVID-19 epidemic has created special conditions in the relationship between the medical staff and patients [13]; furthermore, the need for social distancing and the use of protective equipment on the one hand, as well as an increasing number of patients, especially those with severe illnesses, epidemics, illnesses and dementia and lack of time to provide medical care, on the other hand, has created a different kind of doctor-nurse relationship with the patient that may affect patients' trust [14]. Considering the importance of patients 'trust in physicians and nurses in adhering to treatment and the effectiveness of medical care, this study was designed to compare the level of patients' trust in physicians and nurses in general and COVID-19 wards in a reference hospital in Tehran during the pandemic.

MATERIALS AND METHODS

This study was descriptive and cross-sectional. The study population consisted of patients admitted to both the general and COVID-19 wards of Baqiyatallah Hospital, Tehran, Iran in 2022. Inclusion criteria included the age range of age: 20-70, hospitalization for more than three days in hospital wards, having no serious psychological disorders, and submitting consent to participate in the study. The data collection tools included the patient's trust scale in the nurse and the Wake-Forest physician trust scale. The Nurse Trust Scale has been validated by Nouripour et al [15]. The Physician Trust Questionnaire has been validated by Forati et al [16].

The scale of patient trust in the nurse contains five questions about Responding to the need, Usefulness of measures, Trust in measures and Practice of treatment" and Giving sufficient information to the patient by the nurse with the scales Never, Rarely, Sometimes, Most of the time, Usually, Always". The Physician Trust Questionnaire includes nine questions about Trust in Skills, Treatment Selection, and Physician Decisions on a scale of "Strongly Agree, Agree, Neither Agree Nor Disagree, Strongly Disagree and Disagree".

Patients with more than three days of hospitalization were randomly selected from the ward list. First, patient satisfaction with the study was obtained and then a questionnaire about patients' trust in physicians and nurses was filled in by an interviewer. Data analysis was performed using SPSS-26 software. Descriptive analysis was performed with mean, standard deviation, frequency, percentage, and analytical analysis depending on the type of data with t-test and Chi-square test.

RESULTS

Four hundred patients participated in this study. Descriptive values related to the age of these patients by group and in general are displayed in Table 1. The mean age of patients in the COVID-19 group was 53.3 years and in the Non-COVID-19 group was 53.8 years. This study included 257 male patients (64.3%). In addition, the sex distribution was the same in the two groups of patients with COVID-19 and Non-COVID-19 and no significant difference was observed in the sex distribution of the two groups (P=0.132).

Table 1: Descriptive characteristics of the patients admitted to Covid-19 and non-Covid-19 wards

Variable		COVID-19	Non-COVID-19	P Value
Age (Mean ±SD]		5.3 ± 14.53	3.8 ± 17.53	0.11
Sex	Male	120	137	13.0
	Female	79	65	
Education	Less than a Bachelor's degree	99 (54.1 %)	147 (8.72 %)	<0.001
	Bachelor degree	57 (1.31 %)	49 (3.24 %)	
	Senior	22 (0.12 %)	5 (5.2 %)	
	PhD	5 (7.2 %)	1 (5.0 %)	

In total, 198 patients (49.5%) with COVID-19 and 202 (50.5%) Non-COVID-19 patients were considered in this study. The overall mean of trust in nurses in the COVID-19 group was not significantly different from that of the Non-COVID-19 group.

Most people in both COVID-19 (85.3%) and Non-COVID-19 (86.6%) groups reported that nurses were available, most of the time or always when they needed them.

Most patients in both COVID-19 (99.4%) and Non-COVID-19 (97.4%) groups believed that the nurse's activity was useful to them, most of the time or always. The mean usefulness of therapeutic activities in patients in general wards was 0.1 higher than in patients in COVID-19 wards but this difference was not significant (P>0.05).

Most patients in both COVID-19 (99%) and Non-COVID-19 (95%) groups believed that they trusted the care of nurses always. The average level of trust in medical care for patients in general wards was 0.1% lower than that of patients in COVID-19 wards. But the difference was not significant (P>0.05).

In the COVID-19 group, 93% of patients often or always followed the advice of the nurses, while in the Non-COVID-19 group, 96.5% of patients most of the time or always followed the statements and recommendations of the nurses. The mean rate of treatment of patients with therapeutic recommendations in general wards was significantly higher (0.4) than patients admitted to the COVID-19 ward (P<0.001).

In the COVID-19 group, most patients (71.8%) believed that most of the time, or always, nurses provided enough accurate information about their disease. While in the Non-COVID-19 group, about half of the patients (55%) believed that most of the time or always the nurses provided them with sufficient accurate information about their disease. The average amount of information required for patients in general wards was 0.3 less than for patients admitted to the COVID-19 ward. There was a significant difference in the amount of information required for patients in general wards and COVID-19.

Table 2: Descriptive values related to the trust variables of the patients admitted in the Covid-19 and non-covid-19 wards

Variable	COVID-19			Non-COVID-19		
	SD ± Min	Min	Max	SD ± Min	Min	Max
Responsibility for patient needs	4.6 ± 1.1	2	6	4.6 ± 1.1	2	6
The usefulness of therapeutic activities	8.2 ± 0.5	3	6	8.3 ± 0.5	1	6
Reliability of medical care	3.5 ± 8.0	3	6	2.5 ± 1.1	1	6
Following the recommendations	5±0.9	3	6	4.5±0.9	2	6
Patients' access to the necessary information	4.2± 1.3	1	6	3.9± 1.6	1	6
Satisfaction with the nurse	7.0 ± 9.4	2.6	6	7.0 ± 9.4	2.6	6
Satisfaction with the physicians	3.5±0.3	2.8	4.3	3.7±0.3	2.2	4.5

DISCUSSION

Patients’ trust in nurses and physicians is important and at the same time complex phenomenon that to achieve it, some professional characteristics must be created and strengthened and some ethical principles must be observed [17]. In the study of patients' trust in nurses of Baqiyatallah Hospital, Tehran, Iran, we used the questionnaire of patients’ trust (P=0.006). The results of the study assessing the patients’ trust in the physicians showed that most patients participating in the study in both groups of COVID-19 (92.4%) and Non-COVID-19 (97.5%) had a high level of trust in physicians. Considering the mean difference, it can be said that the average trust in physicians in COVID-19 patients was significantly lower by 0.14 than in Non-COVID-19 patients (P<0.001).

Ravdin and Cabral nurses, which was validated by Nouripour et al [15]. This questionnaire had five questions, and in what follows, we will review the results obtained from the questions.

The level of responding to patients' needs and being available to them when needed, the level of use of treatment activities, and the level of trust in medical care in both general and COVID-19 wards were desirable. The rate of follow-up to treatment recommendations was favorable in both groups, but the mean rate of follow-up to treatment recommendations of patients in general wards was significantly higher than patients admitted to the COVID-19 ward. Studies have shown that there is a positive relationship between the level of trust in the nurses and the level of treatment adherence [18]. Trust in the health care specialist has been proposed as a basis for effective and basic treatments for patient-centered care [19-21]. However, the novelty of COVID-19 and the fact that there is still no definitive cure for the disease is a problem noted in the study by Baker [22]. The lack of definitive treatment and protocol for this disease and frequent changes in health protocols during this period may reflect scientific uncertainty; meanwhile, the uncertainty of scientific evidence reduces patients' trust to follow the recommendations of medical staff compared to other diseases and overshadows their treatment adherence.

In this study, the lowest level of trust was in the average amount of information required for patients, which had a lower score compared to other questions in the questionnaire, and the average amount of information required for patients in general wards was 0.3 less than patients in the COVID-19 ward. Nurses in both the COVID and general wards have the lowest level of patients’ trust in providing the necessary information. In Ozaras and Abaan study, the use of medical terms or terms that the patient does not fully understand, the lack of anticipation or understanding of patients' information needs, and neglecting responsibilities and factors related to nursing work such as busyness, etc. have been mentioned as important causes in reducing the provision of the necessary information to patients [23]. It seems that to improve the provision of information to patients, some programs should be implemented in the hospital and the nursing department.

The level of patients' trust in physicians in COVID-19 wards was significantly lower than in Non-COVID-19 patients. Gupta et al. showed that the pandemic coronavirus disease 2019 (COVID-19) has posed new threats to the trust in medical staff [24]. Factors such as the high prevalence and involvement of doctors during the epidemic peaks, as well as the specific way of communicating with the patient (personal protective equipment and social distancing, etc.] and that the patient does not even know and see the face of the treating physician well, are involved in this issue [25]. Identifying the causes of this difference requires further study and investigation of the issue from different respective.

CONCLUSION

Trust in nurses and physicians in both COVID-19 and general wards was optimum. This finding indicates that during the COVID-19 pandemic, the medical staff worked tirelessly and despite the difficulties and complications of the pandemic, patients have high trust in physicians and nurses.

Abstract: *How people behave in an emergency depends on many social, cultural, and contextual factors. This study aimed to determine the COVID-19 risk perception in Iranian people. This study was descriptive. The study population was the assistant of patients who had come to Baqiyatallah Hospital in 2021. The number of participants was 500. The study tool was the COVID-19 risk assessment questionnaire. Data were analyzed using SPSS-22 software. The mean risk perception score was 2.78(±0.6) on a 7-point scale. The lowest and highest mean of the predictors of risk perception in COVID-19 was trust in government and personal efficacy, respectively. There was a significant difference between men and women in the mean of collective efficacy (P= 0.032). Social knowledge (p=0.007), trust in science (p=0.001), and trust in medical professionals (p=0.050) in positive direct experience people were significantly more than in people with negative direct experience of COVID-19. The most important predictors of risk perception in the COVID-19 epidemic were gender, education, social knowledge, and trust in science (P<0.05). People's perception of the risk of COVID-19 depends on several various factors, the most important factors were gender, level of education, social knowledge, and people's trust in science.*

Keywords: *COVID-19; coronavirus; risk perception*

INTRODUCTION

The coronavirus disease 2019 (COVID-19) is caused by the severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) and has spread around the world quickly, emerging as a significant challenge of the current century for public health, the economy, markets, and policies in many countries [1].

The coronavirus outbreak was declared a public health emergency of international concern by the World Health Organization on 30 January 2020. Today, most people around the world have understood the outcomes of COVID-19 infection and they have accepted the need for hand hygiene and social distancing to prevent its spread. But, some of them ignore or delay hygienic actions, government laws, and social distances in public places, or homes. The fact that individuals in the same situation of common challenge act so differently indicates that the persons' risk perception relating to this new and chronic challenge is strongly different [2].

How people behave in an emergency depends on their understanding of the severity and depth of the risk and the extent of their vulnerability, but many social, cultural, and contextual factors may influence their risk perception [3]. Little is known about how people perceive the risk associated with emerging infectious diseases compared to other areas of risk. Risk perception leads to the adoption of preventative health behaviors so misperception of COVID-19 risk in this condition can lead to negative consequences of pandemic control [4].

Personal experience with the virus, individualistic and prosocial values, hearing about the virus from friends and family, trust in government, science, and medical professionals, personal knowledge of government strategy, and personal and collective efficacy were all significant predictors of risk perception, in the first global assessment of public risk perception of COVID-19 [5].

Previous studies have examined differences in risk perception of COVID-19 in diverse populations and races. Health workers reported higher risk perception, level of worry, and knowledge as related to COVID-19 infection compared to the general population [6]. In some studies, females were found to perceive risks higher, complied more with the government's guidelines, and coped better than males in response to COVID-19 [7]. But Self-reported anxiety over the pandemic is a crucial predictor in explaining risk perceptions in all age and gender groups [8]. And overall public initial concerns and trust can play an essential role in improving the perceived risk of a pandemic and increasing public participation in adopting preventive measures [9]. This study aimed to determine the risk perception score and its related factor in Iranian people.

MATERIALS AND METHODS

This study was descriptive-analytical. The study population was the assistant of patients who had come to the clinic of Baqiyatallah Hospital in 2021. The inclusion criteria were 15 to 80 years old, no serious and acute illness, and consent to participate in the study. The number of participants in the study was 500, with a 5% alpha error and 20% beta error. The study tool was the COVID-19 risk assessment questionnaire, which was designed by Dryhurst [10] using previous studies to identify all dimensions of risk perception covering affective, cognitive, and temporal-spatial dimensions to provide a holistic measure of risk perception. The questionnaire included items on COVID-19 experience, demographic variables (age, gender, and education) knowledge, both personal and social knowledge, social amplification, prosociality, individualism, trust in l three domain of science, medical professionals, and government, personal efficacy, and collective efficacy. The validity of the COVID-19 risk assessment questionnaire was assessed using face and content validity approaches. The impact score of each item was assessed to evaluate the face validity. The questionnaire was distributed among 10 technical experts who were asked to evaluate items based on the mentioned criterion. Then the importance of each item was calculated using the impact score formula and the results were compared with the standard score (1.5), and items whose scores were higher than the standard score were included in the questionnaire. Next, the content validity of the instrument was analyzed using the Content Validity Ratio (CVR) and Content Validity Index (CVI). 10 respondent experts also participated in this phase. Experts were asked to group items as "essential", "essential but not useful", or "not essential" to calculate CVR. Their responses were calculated based on the CVR formula and the results were compared with Lawshe's Table. Numbers higher than 0.6 were approved. CVI survey was done based on the Waltz and Basel content validity index [11]. A questionnaire was distributed among the experts who were asked to rank 24 items based on a four-part Likert scale as compatible with 3 criteria of relevancy, simplicity, and clarity. (For example, unrelated items, partially related items, related items, and fully related items were scored 1, 2, 3, and 4, respectively). Items higher than 0.6 were approved according to the CVI score. Cronbach's alpha method was used to assess the questionnaire's reliability. Data collection was started after the standardization of the questionnaire.

Patients completed the study questionnaire, after written consent. The questionnaire was filled out using the interview method and by a trained interviewer. All information obtained from patients was confidential and the study received an ethics code from the ethics committee of Baqiyatallah Hospital. Primary data were analyzed using SPSS-22 software. Descriptive data analysis was performed using mean and standard deviation in quantitative data and frequency and percentage in qualitative data. Analytical analysis was performed according to the normality of the data with parametric and non-parametric tests. Linear and logistic regression were used to measure the relationship between variables according to the type of data.

RESULTS

The validity and reliability of the instrument of this study

In the first step, the COVID-19 risk assessment questionnaire was validated. Tables 1 and 2 show that the scores of all items of the questionnaire were higher than the criterion score (i.e. 1.5) and experts approved the quantitative face validity of all items. Moreover, the results of CVI indicate that all items of the questionnaire obtained a score higher than 0.6, and content validity was considered appropriate by experts. The reliability of the questionnaire based on Cronbach's alpha was 0.79, 0.69, and 0.77 for risk perception, individualism, and trust in science, respectively.

Study findings

In the study samples, 500 people participated, of whom 253 (50.6%) were women and 247 (49.4%) were men.

The mean age of participants was 38.9 (±11.7) and 147 (29.4%) of the people have experienced the disease. The descriptive characteristics are listed in Tables 3 and 4.

The mean risk perception score was 2.78(±0.6) on a 7-point scale. The lowest mean of the predictors of risk perception in COVID-19 was in trust in the government and the highest mean was in personal efficacy (Table 4).

Table 1: Results of calculating quantitative face validity (impact score) of items of the designed instrument

Item	Frequency	Importance	Impact score
Q1: How worried are you personally about the following issues at present? Coronavirus/COVID-19	0.7	4.4	3.08
Q2: How likely do you think it is that you will be directly and personally affected by the following in the next 6 months? - Catching the coronavirus/COVID-19	0.6	4.1	2.46
Q3: How likely do you think it is that your family and friends in the country you are currently living in will be directly affected by the following in the next 6 months? Catching the coronavirus/COVID-19	0.6	3.6	2.16
Q4: How much do you agree or disagree with the following statements? – The coronavirus/COVID-19 will NOT affect very many people in the country I'm currently living in	0.5	3.6	1.8
Q5: How likely do you agree or disagree with the following statements? - I will probably get sick with the coronavirus/ COVID-19	0.7	3.8	2.66
Q6: How much do you agree or disagree with the following statements? - Getting sick with the coronavirus/COVID-19 can be serious	0.6	3.3	1.98
Q7: How much do you feel you understand the government's strategy to deal with the coronavirus/COVID-19 pandemic?	0.6	3.5	2.1
Q8: To what extent do you think scientists have a good understanding of the coronavirus/ COVID-19?	0.5	3.6	1.8
Q9: Have you ever had, or thought you might have, the coronavirus/COVID-19?	0.6	3.1	1.92
Q10: Have you come across information about coronavirus/COVID-19 from: - Friends and family	0.6	3.4	2.04
Q11: To what extent do you think it's important to do things for the benefit of others and society even if they have some costs to you personally?	0.7	2.2	1.54
Q12: The government interferes far too much in our everyday lives.	0.8	2.6	2.2
Q13: How much do you trust the country's politicians to deal effectively with the pandemic?	0.6	2.5	1.5
Q14: How much do you trust each of the following? – Scientists	0.7	3.3	2.31
Q15: How much do you trust each of the following? - Medical doctors and nurses	0.6	3.2	1.92
Q16: To what extent do you feel that the personal actions you are taking to try to limit the spread of coronavirus make a difference?	0.6	3	1.8
Q17: To what extent do you feel the actions that your country is taking to limit the spread of coronavirus make a difference?	0.7	3	2.1

Table 2: Content validity index of questionnaires through CVR and CVI

Item	CVR	CVI		
		simplicity	perspicuity	relevance
Q1: How worried are you personally about the following issues at present? Coronavirus/COVID-19	1	0.9	0.9	0.9
Q2: How likely do you think it is that you will be directly and personally affected by the following in the next 6 months? - Catching the coronavirus/COVID-19	0.6	0.9	0.8	0.8
Q3: How likely do you think it is that your family and friends in the country you are currently living in will be directly affected by the following in the next 6 months? Catching the coronavirus/COVID-19	0.8	0.7	0.8	0.8
Q4: How much do you agree or disagree with the following statements? – The coronavirus/COVID-19 will NOT affect very many people in the country I'm currently living in	0.8	0.8	0.8	0.9
Q5: How likely do you agree or disagree with the following statements? - I will probably get sick with the coronavirus/ COVID-19	0.6	0.9	0.9	0.7
Q6: How much do you agree or disagree with the following statements? - Getting sick with the coronavirus/COVID-19 can be serious	0.8	0.8	0.8	0.7

Q7: How much do you feel you understand the government's strategy to deal with the coronavirus/COVID-19 pandemic?	0.9	0.8	0.7	0.9
Q8: To what extent do you think scientists have a good understanding of the coronavirus/COVID-19?	0.7	0.7	0.8	0.8

** Correlation is significant at the 0.05 level (2-tailed). ** Correlation is significant at the 0.01 level (2-tailed).*

All predictors were analyzed based on gender variables (the Mann-Whitney U test was used due to abnormal distribution). There was a statistically significant difference between men and women in the mean of collective efficacy (P= 0.032) and the rest were not.

Specifically, people who have had direct personal experience of COVID-19 were different in some predictors of risk perception from those who had no direct experience of disease and social knowledge (p=0.007), trust in science (p=0.001) and trust in medical professionals (p=0.050) in positive direct experience people were significantly more than in people with negative direct experience of COVID-19.

We investigated the determinants of risk perception in regression models. The correlations of demographic variables with risk perception were assessed and gender, as well as education, were significantly associated with risk perception of COVID-19, such that males perceive less risk compared to females (Table 6) and the most important predictors of risk perception in COVID-19 epidemic were gender, education, social knowledge and trust in science (Table 7).

Table 6: Regression output of demographic variables of risk perception in COVID-19

a. Dependent Variable: Risk perception

DISCUSSION

Risk perception is important in determining health-protective behavior. Perception of risk in critical experiences like epidemics is influenced by social, cultural, and contextual factors. Previous experiences such as SARS, influenza, and swine flu epidemic showed that the strategies performed and the results of activities often depend on recognizing the predictors of risk perception and coordinating programs with the important predictors [12]. It should be considered the management of risk perception predictors directs by governments in all programs and activities. The risk perception model recommends in COVID-19 epidemics consist of clusters of variables that correspond to the cognitive tradition (e.g. people's knowledge and understanding of risks), the emotional and experiential tradition (e.g. personal experience), the social-cultural paradigm (e.g. the social amplification of risk, cultural theory, trust, and values), and relevant individual differences (e.g. gender, education, ideology). The mean risk perception score was 2.78(±0.6) in this study which is slightly different from the average risk perception score in other countries. The study of risk perception in ten countries found that the risk perception score of COVID-19 epidemics varied between 4.78 and 5.45 on a 7-point scale, and it is relatively high in countries of the U.K., Spain, and North America. Therefore, in this study, the score of risk perception was significantly lower than in all ten countries. High-risk perceptions may enhance the public's active response to the epidemic. Risk perception is a dynamic process and it changes over time. In this study, more than a year had passed from the beginning of the epidemic, which can be an influential factor in the perception of risk.

In demographic factors, gender was the significant predictor of risk perception. The risk perception score of women was higher than men on all the components of risk perception. Other studies reported the same result and it seems that gender was included as the moderator of risk perception and protective behavior [13]. In similar crises of the past decades, women are constantly seen to be more precautionary behaviors than their male counterparts. Another basic demographic predictor is the level of education of the individual, especially in positive experience persons. In other studies, a high level of educated is more likely to improve the preparedness level and adherence to COVID-19 preventive and control guidelines [14], and poor education was significantly associated with lower risk perception [15], similar to our findings.

The level of education could affect knowledge as well as social knowledge; therefore social knowledge might be an important predictor of risk perception, which was observed in this study. Although studies on COVID-19 have reported associations between social knowledge and risk perception [16], some of them did not find this result [17]. Social knowledge is acquired through socialization and lived experience; however educational guidelines in the media at the national level could affect social knowledge, especially in critical situations such as the COVID-19 epidemic. The basic role of social knowledge in predicting the level of risk perception can be considered in the planning and implementation of national protocols.

This study found that scientific sources were the most trusted sources for COVID-19 information. Similar results were reported in Kwok's study on the COVID-19 pandemic [18] and the prior outbreak of SARS in 2003 [19] and the influenza A (H1N1) pandemic in 2009 [20].

Trust in science and experts in this study was greater than trust in government. The lowest mean of the predictors of risk perception was trust in the government. Trust in the government has been found to influence people's willingness to be accepting preventive activities [21], social limitations [22], and vaccination programs [23]. When people lack the necessary knowledge to evaluate the risk of a hazard, trust becomes an important cue regarding whom to believe and behavior [24]. People need to rely on scientists, professionals, and government agencies to listen and realize the information and the people's trust in these sources might be an important factor contributing to people's acceptance of the difficult precautionary measures needed to eradicate a pandemic [25].

This study might be consisting of some limitations. It should be noted that the study population was limited to those who were referred to the hospital. These people may not be a perfect example of the general population, and it is better to do such research at the national level and with diverse populations. The duration of the research was limited, and it is better to do this research several times.

CONCLUSION

People's perception of the risk of COVID-190 depends on several various factors, the most important of which were gender, level of education, social knowledge, and people's trust in science. It is recommended that studies be performed with larger and heterogeneous populations and longer time.

Abstract: *We aim to introduce a 2022 update on CHD (carcinoid heart disease) considering a multidisciplinary perspective. This is a narrative mini-review. We searched English, full-length papers (PubMed). Inclusion criteria: original articles regardless of the level of statistical significance. We identified 44 papers and manually selected those with CHD, as follows: 8 original studies, 1 case series (N=9 patients), 16 case reports (N=1 patient/paper), and a total of 1,030 patients on published studies. The most remarkable results are the longest period of enrolment of 3-4 decades; CHD ratio among carcinoid syndrome of 37%; 30-day mortality post-cardiac surgery of 12%; median survival in CHD from 1.3 to 3.9 years (more than 2 years if valve intervention is provided); most useful prognostic markers: 5HIIA, NT-pro-BNP, but, potentially, chromogranin A. The specific protective role of somatostatin analogs against developing CHD is yet to be determined. CHD in the absence of carcinoid syndrome/liver metastasis may be related to ovarian NEN (neuroendocrine neoplasia) with a better outcome if prompt intervention. Remarkably, 3 guidelines are released regarding CHD on behalf of ENETS (European Neuroendocrine Tumor Society), and ESC (European Society of Cardiology). CHD still represents a most challenging entity situated at the crossroads of surgery, cardiology, oncology, endocrinology, and gastroenterology.*

Keywords: *carcinoid heart disease, neuroendocrine, serotonin, neuroendocrine neoplasia, carcinoid syndrome, 5HIIA, valve, tricuspid, echocardiography*

INTRODUCTION

The complex field of neuroendocrine neoplasia (NEN), a rare condition with an annual incidence of 2 to 5.1 cases per 100,000 individuals, represents one of the most spectacular domains with massive recent progress from a multidisciplinary perspective [1,2]. The two main direct cardiac complications of NENs' evolution are either heart metastasis or carcinoid heart disease (CHD), also, recently named carcinoid valvular heart disease [3,4]. Primary cardiac NENs are mostly uncommon [5]. While myocardial and pericardial NENs' spreading is unusual (representing less than 1-3% of NENs-related metastases), CHD represents the hallmark of a very severe disease, typically embracing a very poor outcome [6,7]. The advances in cardiac surgery and interventional once-cardiology which have been registered within the latest years improved the overall CHD prognostic, as recently seen in other cardiac surgical procedures [8,9].

CHD is related to hormonally active NENs that increase overall morbidity and mortality; nevertheless, valve intervention might associate with numerous benefits, but carriers of such interventions display additional risks, including the need for post-operative pacing or connected infectious risks [10,11]. The statistical confirmation that the surgical approach to CHD improves survival is currently based on observational data rather than controlled studies [12].

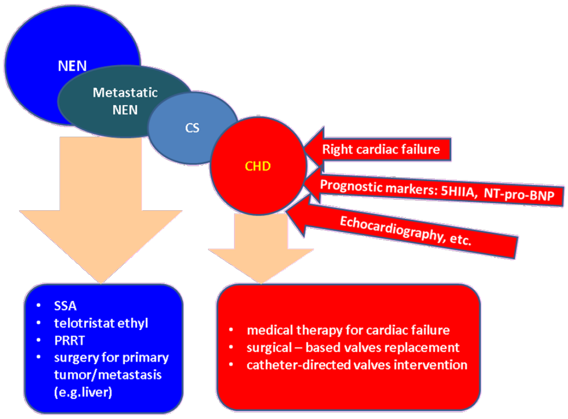
The pathogenesis of CHD is still poorly understood. However, the presence of CHD is closely correlated with abnormal levels of biomarkers (blood and urinary neuroendocrine markers, also, named vasoactive substances which are more than 40 types, despite not testing all of them in daily practice), especially serotonin, and its urinary metabolite 5-HIIA (5-hydroxy-indole acetic acid), but, also, chromogranin A, neuron-specific enolase, etc. which serve as diagnostic tools and prognostic markers as well as part of the surveillance protocols [13-15]. Novel biomarkers like those based on mRNA transcript are currently under development for daily practice implementation [13]. Cardiac imaging is essential for recognizing CHD, from traditional ultrasound to advanced techniques such as speckle-tracking echocardiography, 68 DOTA peptide PET-CT (Positronic Emission Tomography – Computed Tomography) scans, and cardiac magnetic resonance or CT [12,16-18].

CHD almost exclusively targets the right cardiac side with consecutive heart failure, but in the early stages, the complication might be underdiagnosed [19]. The left side of the heart is usually not affected (unless abnormal intra-cardiac shunts) because the fact that the main contributor of CHD, namely serotonin (5-hydroxytryptamine), but, also, histamine, bradykinins, and tachykinins, are enzymatically inactivated into pulmonary bloodstream [19]. Remarkably, in 2018 three cases of quadruple valve replacement were reported in addition to the prior four concerning CHD, which represents exceptional situations in NEN-CHD pointing out that the left heart side may be affected, as well [20].

Usually, at the moment when CHD is identified, the patients already have clinically manifested NEN in terms of traditional carcinoid syndrome (flush, diarrhea, wheezing, loss of appetite and malnutrition, non-specific abdominal pain or cramps, hypotension, telangiectasia, edema, etc.) that is presented in correlation with liver metastases, grossly affecting 30-40% of all NENs [21]. Most patients with CHD are aged between 50 and 70 years (males being slightly more affected than females), and present chronic fatigue and dyspnea, independent of carcinoid syndrome (but may be initially misdiagnosed as carcinoid syndrome or even carcinoid crisis) [19]. The most frequent type of NEN causing CHD is gut-derivate (noting that the small intestine is the most frequent NEN up to 65-67% followed by lung NEN of 25%) and approximately one out of five or two cases (depending on the studied population) is prove to develop CHD which finally influence the prognostic even more than the primary tumor growth itself (in some cases) [12,22]. One meta-analysis from 2021 (including 9 studies, N=416 adults with NEN, mean age of 63 years, 53% males) showed that 75% of CHD – related NENs originate from the small intestine and colon, and 98% of them have synchronous hepatic metastases. Tricuspid regurgitation was confirmed in 97% of individuals of different severities, respective 72% concerning pulmonary valve, while right heart failure was identified in 48% of all cases. After having a valve replacement (99% of tricuspid, and 59% of pulmonary valve), a 30-day mortality of 9% was identified (with a median post-surgery survival of 3 years) which points out an acceptable safety profile of valves intervention in CHD [23].

Overall, the multidisciplinary management of CHD includes cardiologic therapy for heart failure, the control of serotonin excess by using high doses of somatostatin analogs such as octreotide or lanreotide (and/or telotristat ethyl) that act on tumor growth as well, peptide receptor radionuclide therapy in addition to surgery for primary tumor and metastases, especially at the liver site (if feasible) to reduce the tumor burden, and, finally, surgical – based valves replacement or catheter-directed valves intervention in selected patients, depending on various criteria that take into consideration the underlying NEN, the heart status, and the access to cardiac surgery or interventional cardiology [24-28]. Globally, patients with carcinoid syndrome (thus metastatic NENs) and CHD have a more severe prognostic when compare to those without CHD, knowing that NEN individuals with clinically manifested carcinoid syndrome have a more severe prognostic versus those carcinoid free [28,29]. Valve intervention in CHD improves long-term outcomes despite the current peri-operatory mortality rate being considered at 10-20% [29]. Of note, there is no specific medication for CHD other than the medical approach for the originating tumor and associated hormonal panel (NEN's management), on one hand, and cardiologic therapy for heart failure in addition to interventional procedures targeting the affected valves [28-30] (Figure 1).

Figure 1: Sneak peek – carcinoid valvular heart disease



NEN
Metastatic NEN
CS
CHD
Right cardiac failure
Prognostic markers: 5HIIA, NT-pro-BNP
Echocardiography, etc.
SSA
telotristat ethyl
PRRT
surgery for primary tumor/metastasis (e.g.liver)
medical therapy for cardiac failure
surgical – based valves replacement
catheter-directed valves intervention

NEN = neuroendocrine neoplasia; CS = carcinoid syndrome; CHD = cardiac heart disease; 5HIIA = 5-hydroxyindoleacetic acid; NT-pro-BNP = NT-pro-brain natriuretic peptide; SSA = somatostatin analogues; PRRT = peptide receptor radionuclide therapy

MATERIALS AND METHODS

Aim

Our purpose is to introduce a 2022 update on CHD considering a multidisciplinary perspective.

Method

This is a narrative mini-review of literature. We searched English, full-length papers published in 2022 concerning journals indexed in PubMed (by using the terms "carcinoid heart disease"). Inclusion criteria are represented by original articles particularly/specifically addressing CHD (in vivo) regardless of the level of statistical significance (original studies or case reports/series). Exclusion criteria: papers considering heart metastasis in NENs or primary cardiac NENs.

According to mentioned methodology, we identified 44 papers in 2022, and manually selected those with CHD, as follows: 8 original studies, 1 case series (N=9 patients), 16 case reports (N=1 patient/paper), a total of 1,030 patients on published studies, in addition to 8 reviews, 3 guidelines (one with duplicate). We excluded 3 articles concerning non-CHD, one in vitro study, and 3 papers regarding withdrawal (Figure 2).

CLINICAL STUDIES PUBLISHED IN 2022 CONCERNING CHD (accessed via PubMed)

We identified 8 original studies in 2022 (Table 1). A multicenter, retrospective study on 275 patients analyzed the clinical presentation and the outcome in NENs, confirming that more than one-third of the individuals with carcinoid syndrome are affected by CHD. All the patients had carcinoid syndrome (mean age of 57 years, aged between 21 and 84 years; metastatic disease was found in 94.6% of cases). CHD was identified in 37.3% of them (N=104) by using echocardiography, with the tricuspid valve being the most affected cardiac site, single or in combination with other valves. CHD correlated with a poor prognostic in individuals with carcinoid syndrome (similarly, male sex was found to be a risk factor); median survival in the studied population was of 9 years) [31].

Figure 2: The articles included according to the methodology of research

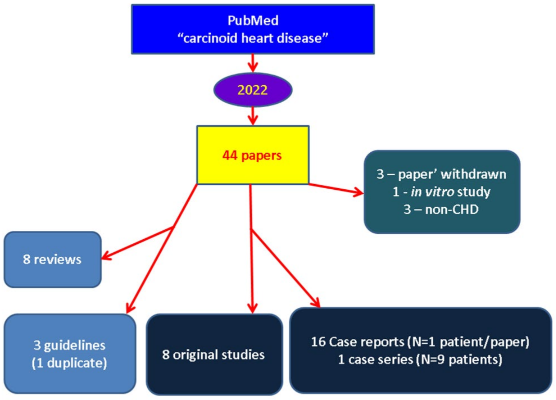


Table 1: Original studies published in 2022 considering carcinoid heart disease

First author/ Reference number	Type of Study	Number of patients	Results
Bergsten J [32]	retrospective (1986 - 2019)	60	30-day mortality (after cardiac surgery)=12% median post-operatory survival = 2.2 years
Levy S [34]	retrospective (1984 - 2021)	84	median survival since CHD diagnostic varying from 1.3 to 3.9 years
Levy S (bis) [35]	validation (case-control) study (1984 - 2021)	114	NT-pro-BNP has the best predictive value for CHD
Kostiainen I [36]	cross-sectional cohort study	65	low rate of CHD (5%) highly sensitive value of echocardiography (not BNP)
Shah HA [33]	retrospective study (2010 - 2019)	17	a 35% decline rate of 5-HIIA in association with liver function improvement
Macfie R [39]	retrospective study (2001 - 2021)	282	overall survival is lower in CHD *versus* non-CHD (N1=40 *versus* N2=242, p<0.001) valve replacement improves survival in CHD + inoperable liver metastasis
Konsek-Komorowska SJ [38]	retrospective study	108	chromogranin A inversely correlates with overall survival (p<0.05) in patients with carcinoid syndrome overall survival is lower in CHD *versus* non-CHD + carcinoid syndrome (67.22 versus 73 months)
Fijalkowski R [31]	retrospective study	275	prevalence of CHD 37.3% among patients with carcinoid syndrome overall survival is lower in CHD *versus* non-CHD

Abbreviations: CHD=cardiac heart disease; BNP=brain natriuretic peptide; N=number of patients

Bergsten J. et al. studied 60 patients (between 1986 and 2019, a total of 3 decades) with a median age of 64 years with CHD and cardiac surgery (N1=42 persons underwent both tricuspid and pulmonary valve replacement; N2=18 individuals had only tricuspid valve replacement with/without pulmonary valvotomy). The procedures (which exclusively used bioprosthetic valves) associated a 30-day mortality of 12%; and a median post-operatory survival of 2.2 years (a maximum of 21 years; statistically significantly higher in N1 versus N2, respective of 3 versus 0.9 years, p=0.02). A most useful tool of prognostic was echocardiography, either as a pre-operatory assessment (but with the limitation of underestimating pulmonary involvement) or post-operatory surveillance. Additional poor prognostic markers are high pre-surgery levels of 5-HIIA and NT-pro-BNP (NT-pro-brain natriuretic peptide). Overall, the double valve is superior to single tricuspid replacement [32]. Moreover, a retrospective UK study (between 2010 and 2019) on 17 patients with CHD who became candidates for valve replacement surgery had a single valve procedure (3/17) versus double valve (13/17), respective triple valve (1/17). Post-operatory, a 35% decline of 5-HIIA witnesses the improvement of general status in association with hepatic function recovery which suggests an indirect benefit of cardiac surgery [33].

Levy S. et al. introduced a cohort study on 84 patients with CHD (58% males) followed for 4 decades (between 1984 and 2021) at Netherlands Cancer Institute; the median age of NEN confirmation was of 62.3 years with a consecutive CHD diagnostic after a median of 1.1 years and an associated median survival varying from 1.3 to 3.9 years (considering the patients who were most recently admitted when valve replacement surgery was more often applied). Prognostic markers are NT-proBNP (positively correlated with tricuspid regurgitation), respective to the implementation of valve replacement surgical procedures (which increases the survival rate) [34]. The same researchers conducted a validation (case-control) study on CHD – associated biomarkers. 114 individuals (N1 with CHD versus N2 without CHD) showed similar age (median age of N1 – 57.9 years, respective of N2 – 59.7 years, p=0.29). Among studied assessments like circulating serotonin, activin A, sST2 (soluble suppression of tumorigenicity 2), CTGF (connective tissue growth factor), and NT-pro-BNP had the best predictive value for CHD in individuals with high serotonin [35].

As opposed to these results, we mention a cross-sectional cohort study on 65 patients with small intestinal NETs (neuroendocrine tumors) (45% with carcinoid syndrome and 5% with CHD). The results showed that both categories had a statistically significant increase in hepatic tumor load, serum levels of chromogranin A, and urinary 5HIIA when compare to the patients without carcinoid syndrome (p<0.005). However, the authors identified a lower rate of CHD (5%) than expected in persons with carcinoid syndrome (30-50% – according to data from the literature). Moreover, they did not confirm the predictive value of proBNP but identified the highly sensitive value of echocardiography in subjects with elevated chromogranin A and 5HIIA [36].

Another classical biomarker in NENs is chromogranin A, very sensitive, but less specific [37]. A retrospective study focusing on blood chromogranin A values (N=108 patients with carcinoid syndrome; N'=84 individuals were followed-up and 27 of them complicated with CHD) showed that its increased levels inversely correlate with overall survival (p<0.05) in patients with carcinoid syndrome. Also, the presence of CHD is statistically significantly associated with a reduced overall survival (67.22 versus 73 months in patients with carcinoid syndrome but CHD-free) [38].

Some authors consider the protective effect of somatostatin analogs like octreotide for CHD, but a large study on 282 patients with carcinoid syndrome (between 2001 and 2021) did not sustain this observation. Overall survival was lower in patients with CHD versus non-CHD (N1=40 versus N2=242, p<0.001). Considering the patients with inoperable hepatic metastasis, the survival rate was lower in patients without undergoing valve replacement when compared to the individuals with CHD and cardiac surgery or the individuals CHD-free [39]. Similarly, we mention a case series of 9 subjects with NEN who followed for 39 months; initially, the patients were CHD-free and started therapy with somatostatin analogs (median time from NEN diagnostic to therapy initiation of one month; median time from starting the medical treatment to CHD confirmation of 23 months) [40]. As far as we currently know, we cannot predict that using somatostatin analogs is a protection factor against CHD, but, of course, this medication has a proven effect in controlling the hormonal and tumor burden [41].

INTERESTING CASE REPORTS

We identified according to our methodology 16 case reports (a total of 16 patients with CHD). We mention the case of a 70-year-old female with torrential tricuspid regurgitation due to CHD regarding an ovarian teratoma with neuroendocrine differentiation. The subject had a heterotopic tricuspid valve replacement with a stable disease within the following 6 months. Mostly particular, the patient did not experience carcinoid syndrome, and neither imaging assays proved any metastatic NEN (including hepatic) after gynecological surgery [42]. Similarly, another case of a large insular primary ovarian NEN was reported on a 40-year-old female admitted for virilization syndrome in association with unexpected CHD – related heart failure; the panel of increased neuroendocrine markers improved after gynecological intervention, but CHD aggravated even in the absence of liver metastasis requiring valve replacement within 6 years [43]. This scenario is extremely unlikely among the typical evolution of NENs, neither ovarian NEN is recognized as a common source of serotonin over-production. However, ovarian carcinoid tumors are among the rarest forms of CHD in the absence of carcinoid syndrome and/or liver metastases, thus their early removal massively improves the survival rate and does not follow within the general frame concerning the very poor outcome in CHD-NENs [44-46].

adequate diagnostic/recognition when she was identified with CHD and had cardiac surgery. The identification of primary NEN was after the intervention for CHD [47]. This case brings out at least two atypical aspects: CHD in young adults, as prior mentioned, which is rather atypical unless a clear genetic background is present, and CHD diagnostic before confirmation of primary NEN [48]. Generally, one-third of NENs remain with unknown primary sources [49]. Theoretically, younger patients with CHD and NEN might have a better post-cardiac surgery prognostic, but further statistical evidence is needed.

A 44-year-old male with neurofibromatosis type 1 had a 6-year history of gastric NET with hepatic metastasis. He was admitted for sensory neuronopathy and a meningocele. After glucocorticoid treatment was empirically initiated, additional decompressive laminectomy was done, but the patient soon developed CHD with a fatal outcome within 3 months (due to pneumonia) [50]. Of note, currently, we do not know the potential role of glucocorticoids (probably recommended for incidental co-morbidities) in aggravating CHD. Moreover, there are no consistent data to point out that individuals with genetic syndromes underlying NEN have a higher risk of developing CHD [51].

As consideration amid the recent COVID-19 pandemic, we mention one case of a 55-year-old male who delayed the presentation and was admitted for severe CHD which was confirmed synchronously with a high serotonin-producing primary NEN [52]. Another case brings out the particular aspects of cardio-oncology practice following valve replacement in subjects with CHD [53]. This is the case of a 58-year-old female who experienced a carcinoid crisis peri-operatory [54]. Another aspect concerns the post-surgery risks, for instance, a 77-year-old woman was offered a successful ablation therapy for recurrent atrial flutter developed after the surgical procedure of replacing the tricuspid valve [55]. Moreover, another case of an 81-year-old male introduces the idea of consecutive interventions in CHD considering the right side of the heart (severe pulmonary regurgitation was successfully approached by trans-catheter implantation 4 years after initial surgery for tricuspid) [56].

DISCUSSIONS

Pathogenic traits of CHD

Hedinger syndrome, tricuspid insufficiency in addition to pulmonary stenosis due to CHD still represents a challenging condition nowadays [57]. CHD is a progressive condition in subjects with carcinoid syndrome where the right side of the heart is transformed in terms of fibrosis, degeneration, inflammation, desmoplastic reactions causing valvar dam-age (stenosis or regurgitation), and cardiac insufficiency [58,59]. The formation of plaque-like deposits (myo-proliferative plaques) on endocardial areas of the valves and subvalvular system impairs the blood flow dynamics [60-62]. Similarly to CHD, mesenteric fibrosis might develop in individuals with carcinoid syndrome [60]. Common pathogenic factors are described like TGF-β (Transforming growth factor beta) or PDGF (platelet-derived growth factor), etc [60].

The clinical approach of CDD

The main predictors of CHD are an advanced stage of NEN with high levels of circulating serotonin but mostly increased 24-hour urinary 5HIIA in addition to the presence of carcinoid syndrome and other clinical features [63-65]. Other collateral elements may involve particular cardiac anatomy, for instance, patent foramen ovale is reported in half of the individuals with CHS (twice more frequently than in the general population) which causes a right-to-left shunting [66,67]. Intra-cardiac shunt explains the left heart involvement in CHD as one case was published in 2022 with four valves involvement [68,67].

Since initially, CHD is subclinical or completely asymptomatic, a strategy of periodic check-ups is necessary, including performing differential diagnostics with other complications of NENs [60,63,69]. Cardiac imaging represents a strong point in CHD management. Ultrasound is useful for serial evaluations and early assessment; CT exams might show various elements like early contrast opacification of inferior cave vein as an indicator of tricuspid regurgitation; modern imaging procedures like 68Ga-DOTATATE PET are helpful for adequate positive diagnostic, especially for cases with a low index of suspicion, when a differentiation with myocardial metastasis or non-NEN incidental conditions is needed [70-72]. One case from 2022 introduced 203Pb-VMT-α-NET Scintigraphy as a new alternative to PET/CT [73].

Full blown picture of heart valve disease – associated clinical manifestations and related cardiovascular and pulmonary complications of NENs including carcinoid crisis represents a sign of advanced disease and prompt multi-disciplinary intervention is required [74,75]. The overall experience with cardiac surgery for CHD is limited when compared to many of the non-CHD causes, thus there are still some areas of open discussion like predictors of successful intervention, the timing of the procedure, criteria of candidates selection, the type replacement (single or double valve) [76-79].

Key messages on behalf of highly specialized medical and surgical societies

In 2022 three papers of major importance were released concerning CHD. European Neuroendocrine Tumor Society (ENETS) published excellent “guidance” regarding carcinoid syndrome and CHD. We mention a few major aspects: NT-proBNP remains the most important marker of CHD at the first-ever diagnostic (in patients who experience high serotonin status with or without clinical manifestation like carcinoid syndrome) and during follow-up. A cutoff value of 260 pg/mL indicates further investigations with echocardiography. In terms of ultrasound, the transthoracic approach is indicated, stress echocardiography might not bring additional information; while inadequate ultrasound data (including the evaluation of pulmonary vein damage) or planning for cardiac surgery may require supplementary imaging procedures like cardiac CT or magnetic resonance. Once identified, CHD requires serial NT-proBNP assays and cardiac ultrasound every 6 to 12 months, noting that sudden progress might occur anytime. Surgery (bioprosthetic valves are advised) should be done in severe CHD with more than 1 year of expected post-surgery survival; some specific criteria are recommended considering the adequate timing of intervention which should not be delayed. Double valve (tri-cuspid and pulmonary) replacement is better than a single one. Minimally invasive procedures are not yet studied enough [80]. Additionally, ENETS introduced a "synoptic" concerning the major role of echocardiography in CHD [81]. A collaboration of ESC (European Society of Cardiology) with other societies provided a guideline on cardio-oncology, also, addressing CHD. We mention some aspects, such as, for instance, echocardiography is recommended in patients with clinical evidence of CHD, carcinoid syndrome, and high BNP followed by a check-up every 3 to 6 months (level IB). BNP is assessed at baseline and every 6 months (level IB). A specific preparation is required considering the surgical/interventional risk of triggering a carcinoid crisis. Valve replacement, as in the ENETS guide-line, is recommended in patients with an expected survival of more than 1 year after intervention if they have symptomatic CHD or asymptomatic CHD (tricuspid or pulmonary) but with progressive dysfunction (level IC, respective IIaC) or severe mitral and/or aortic involvement in symptomatic cases (level IC) [82,83].

CONCLUSIONS

CHD represents a most challenging entity situated at the crossroads of surgery, cardiology, oncology, endocrinology, and gastroenterology. Until a few years ago, CHD was synonymous with a very severe form of NEN/carcinoid syndrome, with an expected poor outcome and limited resources. Recent cardio-oncology progress in addition to multiple shaped interventions for NEN allows a new level of approach in CHD to the benefit of the patients. However, many aspects are still open issues even in 2022.

List of Abbreviations
5-HIIA = 5-hydroxyindoleacetic acid
NEN = neuroendocrine neoplasia
CHD = carcinoid heart disease
NT-pro-BNP = NT-pro-brain natriuretic peptide
PET-CT = Positronic Emission Tomography – Computed Tomography
TGF = Transforming Growth Factor
PDGF = platelet-derived growth factor
NET = neuroendocrine tumor
NEN = neuroendocrine neoplasia
sST2 = soluble suppression of tumorigenicity 2
CTGF = Connective Tissue Growth Factor
ENETS=European Neuroendocrine Tumor Society
ESC=European Society of Cardiology

Abstract: *Collision tumors, rare neoplasms underlying two distinct histological types of carcinomas (with different origins) separated by normal tissue, are described in many organs including the thyroid gland, but to a lesser extent. We aim to overview the current published data concerning collision tumors of the thyroid (CTT). This is a narrative review considering papers published on PubMed through a search starting from the terms "collision" and "thyroid". Inclusion criteria are full-length articles, the English language, the timeline from inception to December 2022, and original studies with different levels of statistical evidence. We followed the main types of thyroid carcinomas: differentiated thyroid carcinoma of papillary and follicular type, anaplastic/ undifferentiated/poorly differentiated carcinoma, respectively medullary thyroid carcinoma. We identified 92 papers based on the mentioned key words criteria. We excluded 54 papers (reviews or non-thyroid CTT or other topics outside our purpose). We included in the final analysis 38 papers: 34 case reports (1 patient per paper), 2 case series (2 individuals per each article), one case series of 3 subjects, and a single study of retrospective type (including 21 subjects) – a total of 62 patients on published cases which represents the largest study on published cases to our knowledge (according to our methodology).*

Keywords: *collision, thyroid, thyroid cancer, papillary carcinoma, follicular carcinoma, medullary thyroid cancer, thyroidectomy, pathological report*

INTRODUCTION

Collision tumors, rare neoplasms underlying (at least) two distinct histological types of carcinomas (with different origins) separated by normal tissue (and no mixture areas), are described in many organs (for instance, lung, stomach, breast, and ovary, etc.) including the thyroid gland, but to a lesser extent than seen in others sites (affecting less than 1% of all thyroid malignancies) [1-3]. The most common combination is papillary and medullar carcinomas, but any type of primary thyroid malignancy is reported in collision with a secondary spreading to the thyroid from a non-thyroid primary cancer or another primary type [4-6].

Collision tumors of the thyroid (CTT) are regarded as challenging in terms of recognition, poor outcome elements, and particular behavior in addition to the fact that there are still areas of the unknown regarding this chapter on thyroid neoplasms [7-9]. A distinction with composite tumors should be done (where the same mutation causes histologically different entities) [10-12]. Also, metachronous tumors (syndromic or not) represent a different category [13-14].

We aim to overview the current published data concerning CTT**.**

MATERIALS AND METHODS

This is a narrative review considering papers published on PubMed through a search starting from the terms "collision" and "thyroid". Inclusion criteria are full-length articles, the English language, the timeline from inception to December 2022, and original studies with different levels of statistical evidence. Exclusion criteria are non-thyroid collision tumors, non-English papers, and reviews. We followed the main types of thyroid carcinomas: differentiated thyroid carcinoma of papillary and follicular type, anaplastic/undifferentiated/ poorly differentiated carcinoma, respectively medullary thyroid carcinoma**.**

RESULTS

We identified 92 papers based on the mentioned key words criteria. We excluded 54 papers (reviews or non-thyroid CTT or other topics outside our purpose). We included in the final analysis 38 papers including 34 case reports (1 patient per paper), 2 case series (2 individuals per each article), one case series of 3 subjects, and a single study of retrospective type (including 21 subjects) – a total of 62 patients on published cases which represents the largest study on published cases to our knowledge (according to previously mentioned methodology) (Figure 1).

Figure 1: The method of research considering collision tumors of the thyroid

Papillary thyroid carcinoma

Papillary thyroid carcinoma is the most frequent histological type in CTT, but, generally as a single entity, it represents the most common thyroid neoplasia [15]. Apart from the most often association of medullary thyroid neoplasia, follicular malignancy is reported as well [16-19]. The combination with thyroid metastasis (typically from lung, breast, or renal cancers, etc.) is reported at the level of case reports (the spreading may be by local extension or via blood mainstream) [20-21]. For example, a case from 2007 introduced a CTT consisting of metastasis from lung adenocarcinoma and papillary thyroid cancer in a 63-year-old female [20]. A case report from 2021 included a 60-year-old female who was identified with the same carcinoma and metastasis from osteosarcoma within a CTT. This is the first case with bone origin as the primary source reported in a CTT [21]. The combination with a second primary cancer which is not originating from the thyroid is also reported. We identified a single case of a 67-year-old male who was diagnosed with a CTT associated a papillary thyroid cancer (with lymph node metastases) and parathyroid carcinoma clinically manifested with primary hyperparathyroidism [22]. The co-existence of a squamous cell carcinoma was reported, as well, originating from different sites or of unknown origin [23-27]. In 2004, a most unusual association with metastatic liposarcoma was published (this represents a most unique combination) [28].

Follicular thyroid carcinoma

This is the case of a 62-year-old female with follicular carcinoma (with capsular and vascular invasion) in association with a mucoepidermoid carcinoma and distant metastasis. Immunohistochemistry report might identify the mucoepidermoid differentiation of follicular malignancy over a different histological type (like mucoepidermoid malignancy) [29]. Hürthle cell carcinoma (regarded as a type of follicular group of differentiated thyroid cancers) is reported in less than 3% of thyroid malignancies, with the same ratio (of 3%) being reported for medullary thyroid carcinoma, as well. Their combination was identified on a 70-year-old female as a CTT (of note, the medullary cancer was intra-thyroidal, while the lymph nodes extension was derivate from Hürthle cell carcinoma) [30].

Interestingly, one retrospective study on 8 patients diagnosed with a primary thyroid malignancy identified the co-presence of the second histological type, meaning a follicular thyroid adenoma in association with papillary thyroid carcinoma (7/8), respectively medullary thyroid carcinoma (1/8) [31]. However, the current definition of CTT includes two malignant tumors, either primary or secondary, not a benign one like a follicular adenoma (which cannot be differentiated from a follicular carcinoma through the cytological report and it requires histological assessment) or a non-tumor – related cyst [31,32].

Medullary thyroid carcinoma

CTT may concern the thyroid gland and/or associated lymph nodes [33,34]. For instance, there is a case published in 2021 involving a 27-year-old male presenting CTT at lymph nodes (central compartment) from papillary thyroid cancer and non-syndromic medullary thyroid cancer. The growth speed was evaluated and the authors suggested that it may be similar to what we prior know concerning each of the two malignancies [35]. Generally, collision metastasis (mostly at cervical lymph nodes) is rarely reported in the absence of a thyroid tumor itself. We identified two papers concerning collision metastasis from papillary thyroid cancer and breast malignancy in female subjects [36,37]. In another case, a 73-year-old male was admitted for collision metastasis (cervical lymph nodes) from squamous cell carcinoma of nasal origin and B-cell lymphoma [38]. A previous report from 2009 included a lymph node spreading from a primary follicular malignancy and a squamous cell carcinoma of unknown origin [39]. Moreover, we mention the case of a 47-year-old male with collision metastasis from oral tongue–related squamous cell carcinoma and accidentally detected thyroid papillary carcinoma [40].

However, we currently do not have enough statistical evidence to compare the evolution in CTT versus non – CTT cases. The largest study particularly addressing CTT is a retrospective analysis that included the experience from 2009 to 2019 (a 10-year experience) on a tertiary care cancer. CTT (medullary + papillary) represented 4.7% of the medullary cancer series (N=21 individuals, the sex ratio of 1; mean age of 45.33 years, range between 26 and 77 years). 66.66% of the papillary cancers were situated at the right thyroid lobe; 85.7% of them were of micro-papillary type. The mean size of medullary cancer was three times larger than differentiated thyroid tumors. The contribution to lymph node spreading (which was confirmed in 76.2% of cases) was done by medullary type (87.5%), papillary cancer (12.5%), respectively both malignancies (12.5%) [41].

Anaplastic, undifferentiated, and poorly differentiated thyroid carcinoma

In 2022 Gupta RK. et al. reported the case of a 55-year-old female with a most unusual CTT: anaplastic thyroid malignancy (osteoclastic variant) and primary squamous cell carcinoma, each affecting a different thyroid lobe in addition to distant metastases at the level of bone, muscle and lymph nodes. However, according to WHO (World Health Organization) 2022, these two types are parts of the same malignancy spectrum thus their combination is nowadays regarded as a CTT-like lesion [42].

The "late anaplastic shift" theory concerns the identification of anaplastic thyroid carcinoma on a subject with a long history of differentiated thyroid carcinoma (either papillary or follicular) [43]. However, the synchronous identification of a differentiated tumor in association with a poorly differentiated cancer respecting a border area between them is consistent with the current concept of CTT. Here we mention the case published in 2021 by Vlad M. et al. (a 56-year-old female admitted amid the COVID-19 pandemic with a post-thyroidectomy confirmation of anaplastic cancer on the left lobe and lymph nodes spreading and a papillary micro-carcinoma on the right lobe) [44].

The presence of two highly aggressive malignancies in CTT makes the prognostic extremely severe. There is the case of a 63-year-old female confirmed with a triple CTT: poorly differentiated carcinoma, papillary carcinoma (classical and hobnail variant – this is the first case report underlying this subtype in CTT), and oncocytic (Hürthle cell) carcinoma. The hobnail pattern has been reported in anaplastic and poorly differentiated thyroid malignancies, representing a sign of a very aggressive profile with rapid evolution [45].

DISCUSSION

Pathogenic loops in collision

The field of thyroid surgery is extremely complex, while the domains of pathological reports underlying thyroid neoplasia are also extremely vast and dynamic [46-48]. The collision phenomenon has been described at many levels within multiple organs of the human body [49]. "Chance" theory is one pathogenic hypothesis [41]. CTT might be underdiagnosed, especially micro PTC [41]. Fine needle aspiration (cytological report) might not identify both tumors. However, immunohistochemistry and molecular studies might help the diagnostic [50].

Whether different immune or genetic co-morbidities might act as a trigger or epigenetic elements for CTT development there is still an open question. We mention a case of CTT (papillary and medullary neoplasia) in a 46-year-old female with multiple sclerosis and prior therapy with interferon. This is the first case of CTT on a patient with this neurologic condition (published in 2020) and there is still missing information about a potential pathogenic loop [51].

Common genetic background of both tumors underlying CTT is reported in some cases. For instance, there is the case of a 69-year-old woman with Hürthle cell carcinoma (on the right lobe) and multi-centric papillary cancer (on both thyroid lobes), associated with BRAF mutations (V600E gene) [52].

Also, in 2010, a case of non-multiple endocrine neoplasia medullary cancer in addition to papillary malignancy underlying CTT was reported in a female carrying a particular RET mutation (familial medullary thyroid cancer) [53]. A RET somatic point mutation in association with mixt medullary–papillary (including a follicular variant of papillary cancer) neoplasia was described in a 59-year-old male (a case published in 2007) [54]. Earlier data also suggest this theory [55]. Moreover, the co-presence of granulomatous inflammation in a case of papillary–medullary malignancy might represent the hallmark of common pathways [56].

Early reports of CTT

Of historical note, we identified the first report regarding CTT on PubMed in 1977 (non-English paper) [57]. The first English paper concerning a single case with medullary and papillary neoplasia is dated 1989 [58]. The first case series (2 out of 3 cases) on PubMed with the same mix of neoplasia is published in 1994 [59]. The first CTT with collision metastasis published in a PubMed – indexed journal dates from 1996 [60]. The first triple CTT (on PubMed) was reported on a 27-year-old female with papillary, follicular, and medullary carcinoma [61].

The literature-based analysis

Overall, we identified 62 cases on published data concerning CTT, thus we may say that this particular entity remains at the level of case reports. However, paying attention to this most unusual neoplasia might improve the prognostic and help early detection of at least one of the tumors. With one exception, all cases included at least one differentiated thyroid malignancy, either papillary or follicular (including 3 cases of Hürthle cell/oncocytic carcinoma). Five reports were consistent with the concept of collision metastasis concerning local lymph nodes (near the thyroid). 16/38 articles included medullary thyroid cancers. Based on these data, following differentiated (papillary being the most frequent) and medullary types, elements of squamous cell carcinoma originating from different organs were more frequent than anaplastic/poorly differentiated carcinoma. As mentioned, the most uncommon elements in CTT were: metastatic liposarcoma and osteosarcoma, respectively, and parathyroid carcinoma. All reported cases are adults (we did not identify any pediatric cases). The age varied between 26 and 88 years. More than half of the papers included female patients, but the single study we have so far reported an equal prevalence between males and women (Table 1).

Table 1: Published cases on collision tumors of the thyroid according to our methodology; the cases are displayed from the most recent starting with 2022 (please see references in the text according to first column indices)

We currently do not know if any data concerning the age or the sex of the subjects should be regarded as risk factors. In addition to the lack of poor survival indices (which are relevant in metastatic cases, those with late diagnostic, and anaplastic/poorly differentiated tumors), the underlying mechanisms are controversial and we need further histological, molecular, and genetic studies.

CONCLUSIONS

The current limits of the CTT field are correlated with the small size of published data until the present time. We still need markers of poor prognostic. Awareness is essential for early detection with a consecutive potential improvement of the outcome.

Abstract: *The recent increase in life expectancy is the main argument for a better understanding of the pathophysiological mechanisms underlying aging. These, once known, can provide possible links to therapies to prevent aging or slow down the process. Normal aging is associated with a progressive decrease in the glomerular filtration rate. Accurate estimation of GFR in the elderly is under the suspicion of multiple errors mainly due to sarcopenia and decreased protein intake. Differentiation between chronic kidney disease and the physiological decline of GFR might be a challenge in clinical practice and this has consequences on the evolution and treatment of the numerous comorbidities of the elderly. The current trend to use non-invasive diagnostic techniques explains the need to identify a serological marker to help differentiate between decreased GFR secondary to kidney aging or the development of chronic kidney disease.*

Keywords: *elderly, normal kidney aging, chronic kidney disease*

INTRODUCTION

Globally, there is a progressive aging of the population.

According to the United Nations Report, 1 in 11 people was over 65 years old in 2019 and it is estimated that in 2050, 1 in 6 people will be this age [1].

The aging process affects the whole body and is characterized by structural changes and functional decline in all organs, leading to an increased incidence of many diseases considered "specific to the elderly". Among these changes, the aging-associated alterations in both structure and function of the kidney are particularly important, having consequences on the evolution and treatment of the numerous comorbidities of the elderly.

Accurate quantification of kidney function in the elderly is difficult, both overestimating and underestimating the glomerular filtration rate (GFR) being possible with currently available serum creatinine-based calculation formulas.

AGING KIDNEY PROCESS

An accurate description of histological changes in the senile kidney, i.e. changes attributed to advanced age per se, is difficult because the elderly usually accumulate important comorbid burdens with impact on the kidney structure and function: diabetes, hypertension, heart failure, etc. Many of the terms that describe physiological changes in the aged kidney superimpose with terms that describe renal pathological processes: nephrosclerosis, tubulointerstitial sclerosis, glomerulosclerosis, arteriosclerosis, etc.

Macroscopically, starting from the 4th decade of age, the kidneys begin to decrease in size and weight progressively, so that around the 7th decade there is a reduction by about 20-30% of kidney weight compared to the age of 40 years [2]; in the elderly without kidney disease, the decrease in kidney size is symmetrical. Also, with age, the kidney's cortex becomes thinner and rougher, the number and size of benign cysts increases, and the pelvis is enlarged with more fatty infiltration. The scarring is more advanced when associated with aortic and renal atherosclerosis (Figures 1 – 5) [3].

Microscopically, starting with the 5th decade of life, there is a progressive decrease in the total number of nephrons due to sclerosis of all nephron compartments [3]: glomerulosclerosis, tubulointerstitial sclerosis, and arteriosclerosis.

The prevalence of glomerulosclerosis increased from 25% in the 3rd decade of life to 82% in the 8th decade [4], the main cause being arteriosclerosis of the small intrarenal arteries.

Figure 1: 87 years old male: granular surface with increased scarring

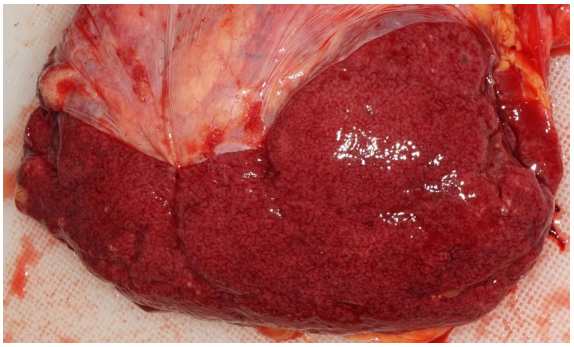

Figure 2: Same case, yellow arrows: small stones, thinning of the cortex

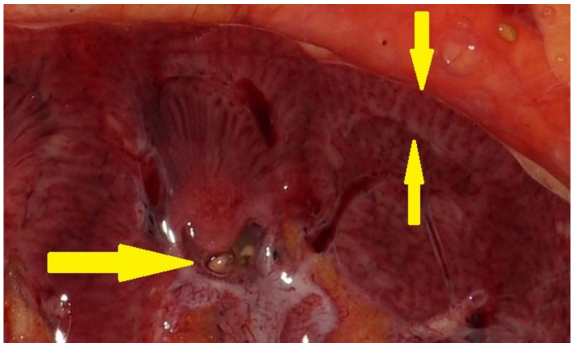

Figure 3: Same case, yellow arrows: glomerulosclerosis (10X HE)

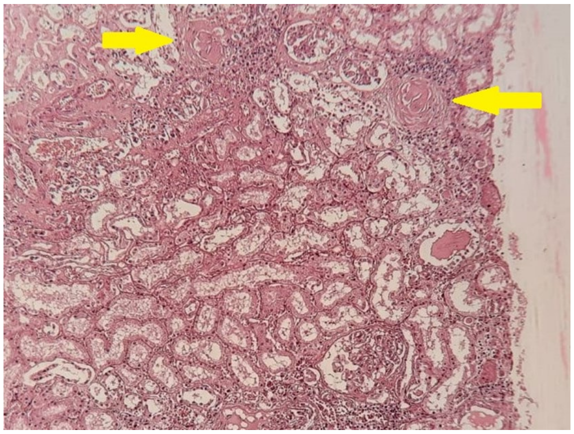

Figure 4: Same case, yellow arrows: arterial wall thickening (10X HE)

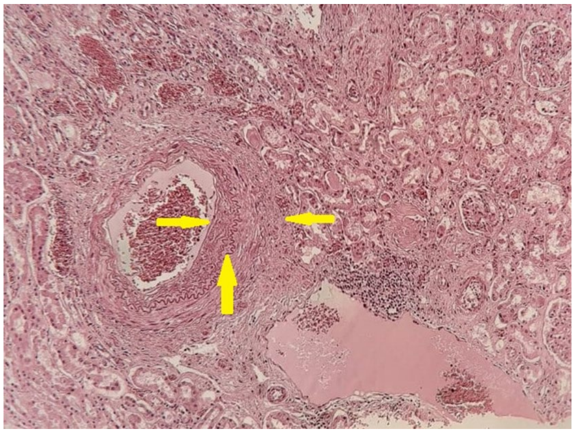

Figure 5: Same case: interstitial sclerosis (10X HE)

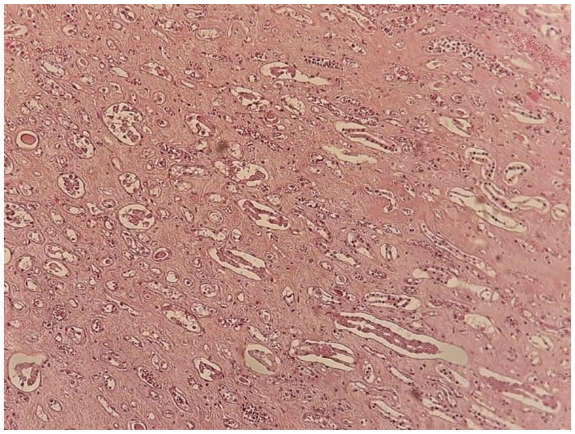

The hallmark of the functional decline of the senile kidney is a progressive decrease in the glomerular filtration rate (GFR) [5]. The decline in GFR begins around the 4th decade of life; between the 8th and 9th decades, the GFR is over 45% lower than at the age of 40 [3,6].

ESTIMATED GLOMERULAR FILTRATION RATE (eGFR) IN ELDERLY

There is no consensus regarding the optimal equation for the estimation of GFR in the elderly. Formulas used in clinical practice in adults – MDRD (Modification of Diet in Renal Disease, CKD-EPI (Chronic Kidney Disease – Epidemiology Collaboration), Cockroft-Gault are all based on serum creatinine levels and they have not been all validated for individuals older than 70 years.

Creatinine-based equations for GFR estimation have several drawbacks in older individuals [7]. Due to age-associated sarcopenia, there is a reduced release of creatinine from the muscles, therefore also a reduced urinary excretion of creatinine [8]. In elderly diabetics, especially in the late-elderly group (75 years or older), it has been noted a more decreased serum creatinine when compared with non-diabetics and this observation was explained by the increased loss of muscle mass promoted by diabetes [9]. Also, the elderly tend to have a reduced intake of proteins and a decreased basal metabolism, therefore, they have supplementary causes for the reduced production of creatinine [10]. Increased metabolism of creatinine by intestinal microorganisms may be an additional cause for reduced levels of serum creatinine, as there are proven age-related alterations of gut microbiota [11]. Formulas using the patient’s weight besides serum creatinine give more errors due to increased fat percentage in the organism of the elderly. Several researchers had concluded that both MDRD [12] and CKD-EPI [13] formulas tend to overestimate GFR in the elderly, while Cockroft Gault's [14] formula underestimates it [15,16].

Serum creatinine alone is often used in clinical practice not especially for estimation of GFR, but for monitoring the patient during treatment with a potential nephrotoxic agent (aminoglycosides for example) or a potential ischemic renal insult (cardiac surgery for example). Besides the fact that this conduct is not correct due to the late and modest increase of serum creatinine level compared to the moment and degree of kidney insult, in the elderly, it is a source of supplementary severe misjudgments. The elderly have often lower basal serum creatinine and during an injury renal process, an increase of serum creatinine remains in the range of the normal values of the laboratory and this result may be misinterpreted as a stable state, i.e. no iatrogenic. Moreover, the creatinine increase may be blunted by intensive hydration of the patient applied to minimize the kidney insult.

Formulas based on both serum creatinine and serum cystatin C have been proposed to overcome the disadvantages of formulas based only on creatinine values [17]. Nevertheless, serum cystatin C is influenced not only by kidney function, but also by several diseases often present in the elderly, such as atherosclerosis, inflammatory estates, or obesity [18,19].

Several alternative equations have been developed for older individuals. The HUGE formula (Hematocrit Urea GEnder) was developed in 2011 by a group of researchers from Spain to differentiate patients without CKD from those with CKD [20]; this formula was validated in some studies [21,22].

L = 2.505458 - (0.264418 x hematocrit) + (0.111800 x blood urea); 1.383960 is added for the male patient. For L <0, CKD is excluded; for L> 0, it is classified as CKD.

In 2012, the Berlin Initiative Study (BIS) introduced two new formulas based on serum creatinine and serum creatinine plus serum cystatin C, respectively, for estimating GFR in people over 70 years of age [23].

BIS 1: eGFR = 3736 x serum creatinine-0.87 x age-0.95; in women, the result is multiplied by 0.82.

BIS 2: eGFR = 767 x cystatin C-0.61 x serum creatinine-0.40 x age-0.57; in women, the result is multiplied by 0.87.

Although these formulas have been validated in some studies, there are no large trials to conclude their superior performance, therefore meanwhile guidelines recommend using the same equation as in the general adult population.

NORMAL KIDNEY AGING VERSUS CKD IN ELDERLY

Reported data on CKD prevalence in the elderly is impressive. A highly cited source in the literature is a meta-analysis performed by Hills and collab. which comprises more than 100 reports from all continents; according to this meta-analysis, the prevalence of CKD in all stages in the general population is 13.4% (11,7-15.1%), but increases to 27.6% (range 26.7-28.5%) in the 6th decade and 34.3% (31.9-36.7%) in the 7th decade of life. The same source also revealed increased CKD stage 3-5 in the elderly: from 10.6% in the general population (9.2-12.2%) to 11.3% (8.1-14.5%) in the 6th decade and respectively to 27.9% (16.4-39.3%) in the 7th decade [24]. Nevertheless, a large proportion of the geriatric population meets the KDIGO criteria for CKD even without markers of renal impairment [25,26]. Regardless of the formulas utilized to estimate GFR, an important question needs to get answered in the face of an older patient with abnormal GFR and no markers of kidney disease. Is it CKD without markers of kidney disease or is it normal kidney aging? Several reasons require a response to this question. Establishing a diagnosis of CKD imposes close monitoring of the patient and adequate preparation for conservative or dialysis treatment. Most of the patients aged >65 years have estimated GFR between 45-60 mL/min/1.73m^2; older patients with estimated GFR between 45-60 mL/min/1.73m^2 have, in comparison with younger adults, decreased risk to progress to end-stage renal disease (ESRD), but increased risk to die from other diseases until they reach ESRD [27,28]. Close nephrological monitoring of all these patients would be a significant burden for physicians, and also for the health systems. On the other hand, CKD, even oligosymptomatic, is associated from early stages with increased risk for cardiovascular events and cardiovascular mortality; specific complications of CKD, such as acidosis or increased parathormone (PTH) have early onset and need to be controlled.

There are several subtle clues allowing the differentiation between the physiologic decrease of GFR and CKD (Table 1).

Serum urea and creatinine increase late in the course of CKD in all patients, but especially in elderly patients. Low serum creatinine levels are observed due to decreased basal metabolism, reduced protein intake, and sarcopenia [3], therefore CKD may be present with normal values of serum creatinine in the elderly. However, the aging kidney excretes increased amounts of urea, due to the reduced density of urea channels in the collecting tubes [29]; a normal serum urea level is associated with normal aging [15].

Table 1: CKD versus normal kidney aging

	CKD	***Aging kidney***
Nitrogen waste products in the blood	Increased	Normal
Albuminuria	Present	Absent
Anemia	Present (erythropoietin deficiency)	May be present (nutritional anemia)
Acid-base balance	Metabolic acidosis	Normal
Ca-P metabolism	Hypocalcemia decreased active vitamin D, increased PTH	Possible hypocalcemia, normal PTH, normal active vitamin D

No anemia should be present as in healthy older populations erythropoietin (EPO) production is normal or even increased secondary to increased erythrocyte turnover, increased EPO resistance, or as a response to occult digestive blood losses [30,31]. Nevertheless, in clinical practice, the elderly have often nutritional mild/moderate anemia that may be misinterpreted as CKD-associated anemia. Reduced secretion of EPO in CKD is associated with normocytic and normochromic anemia, while nutritional anemia is often hypochromic and microcytic [32], but they may coexist.

No abnormalities of mineral metabolism are present in healthy older individuals. Renal tubular excretion of calcium, magnesium, and phosphorus is not altered in healthy elderly [5,33]. The elderly are prone to hypomagnesemia, but this seems to be mainly due to reduced dietary intake, decreased intestinal absorption of magnesium, and/or laxative abuse [5]. Although the elderly present more often with mild hypocalcemia, it occurs mainly secondary to native vitamin D deficiency through reduced sun exposure or decreased skin synthesis of vitamin D [34]. In contrast with CKD, there is no deficiency of active vitamin D, nor an increased synthesis of parathormone in healthy elderly.

Under basal conditions, the kidneys of the elderly have a normal capacity for the excretion of acids and the acid-base balance does not undergo significant changes even with a normal- or hyper-protein diet [35]. However, the renal reserve of the elderly is reduced and a rapidly installed high acid load may be difficult to be compensated by the senile kidney; the elderly are highly vulnerable to the side effects of acute metabolic acidosis (uncontrolled diabetes, sepsis, acute kidney injury).

On the other hand, the presence of albuminuria is a strong argument for CKD even if the patient has other comorbidities that may explain this finding (systemic atherosclerosis, diabetes, cardiac failure). Albuminuria is associated with an increased risk of progression of CKD [36], therefore applying antiproteinuric measures might have the same benefits in the elderly as in younger adults, i.e., attenuating the progression of CKD and reducing cardiovascular events [37]. Nevertheless, overzealous administration of RAAS inhibitors in the elderly is associated with an increased risk of side effects (hypotension, hyperkaliemia, acute kidney injury) in the presence of reduced GFR and systemic atherosclerosis or other comorbidities; another reason why these drugs are no longer needed in elderly without proteinuria is the fact that they become useless, not having time to install their renoprotective effect over time [38,39]. The elderly are prone to hyperkaliemia even in the absence of reduced GFR due to the low sensitivity of distal tubules to aldosterone [31,40].

Taking into account that the elderly have a higher risk of death due to various complications than to progress to ESRD, there is a need to assess individual risk for these outcomes to analyze treatment options and make early plans for conservative treatment (diet, prevention, and control of uremic syndrome with medication) or renal replacement therapy. CKD has an extremely heterogeneous presentation in the elderly; between an independent full-functioning person without cognitive impairment and without major comorbidities at one pole to a frail, immobilized in-bed individual with severe cognitive dysfunction, multiple disabling comorbidities and total dependence for medical care at the other pole, there are numerous clinical pictures. One such equation was proposed by Tangri et al in 2011 who developed the Kidney Failure Risk Equation (KFRE) using variables like age, sex, estimated GFR, albuminuria, serum calcium, serum phosphate, serum bicarbonate, and serum albumin to predict progression toward ESRD after 1, 3 and 5 years respectively for patients with CKD stages 3 to 5 [41]; a variant using only 4 variables (age, sex, estimated GFR and albuminuria) may be used, but the results offer less accuracy [41]. This model has not been designed especially for older individuals, but it has been validated both for patients < 65 years and those above this age and for various races [42,43]. Calculation of this score is available on the internet at http://www.qxmd.com/Kidney-Failure-Risk-Equation. KFRE is recommended by European Renal Best Practice Group to be used in elderly with an estimated GFR < 45 mL/min/1.73 m^2 to assess progress toward ESRD [44]. Nevertheless, a lot of old individuals are placed in the range of GFR between 45-60mL/min/1.73 m^2 and have no markers of kidney disease (albuminuria) [45]; there are no available validated prediction models for this situation and members of European Renal Best Practice Group opine for the urgent need of such prediction models.

Regarding the prediction of death, in the literature there are numerous scores specially designated for the old population and most of them also include, besides demographic variables (age, gender) and comorbidities (heart failure, diabetes, active neoplasia, anemia, history of stroke, chronic obstructive pulmonary disease, etc.), a marker of kidney dysfunction such as estimated GFR or urinary albumin/creatinine ratio [46-49]. These models estimate the risk of death at periods ranging from 3 months to 5 years. The European Good Practice Guideline recommends the use of the Bansal score in current practice for assessing the risk of mortality of non-fragile, un-institutionalized elderly people with CKD >stage 3b [44,47]; this score uses 9 variables - age, sex, GERD, urinary albumin/ creatinine ratio, smoking, diabetes, heart failure, history of stroke; according to this predictive model, the 5-year mortality varies between 3.8% for individuals with lower scores to 83.6% for individuals with all 9 items reached. Nevertheless, again, none of these models took into analysis the particular situation of individuals with normal kidney aging, i.e. those patients without markers of kidney damage and GFR between 45-60 mL/min/1.73m^2. We found in the literature just one publication, that of Van Pottelbergh and collab. who analyzed mortality of very old (>85 years) individuals with GFR> 60 mL/min versus those with GFR between 45-60 mL/min [50]. According to the authors of this paper, the combination of the baseline estimated GFR and the estimated GFR slope over 3 years can be used to assess the risk of death; in the subgroup of patients having estimated baseline GFR between 45-60 mL/min only those with a GFR decrease ≥ 5 mL/min/year had an increased risk of death, while among patients with baseline GFR > 60 mL/min, a decrease of ≥ 3mL/min/year was associated with increased risk of death. The same authors explained that these changes are a reflection of cardiovascular damage. Also, the authors share the opinion of a lot of others those older adults with GFR between 45-60 mL/min should not be classified as moderate stage 3 CKD.

CONCLUSIONS

Aging associates the functional decline of all tissues and organs secondary to degenerative structural changes. Normal kidney aging is a complex process that is difficult to be differentiated in clinical practice from chronic kidney disease with contemporary available criteria; both share the reduced glomerular filtration rate as the main feature. Nevertheless, it is important to make this differentiation.

Establishing a diagnosis of CKD imposes periodic nephrology consultation for monitoring the progression of the disease, treatment of complications, early planning of conservative or dialysis treatment, and also adjustment of treatment of multiple comorbidities of the elderly. CKD has multiple complications and requires often interdisciplinary care: cardiologists, neurologists, psychiatrists, nutritionists, etc. On the other hand, proving that reduced GFR is only a sign of normal aging and that there are no markers of kidney damage allows gerontologists to provide holistic care for slowing the aging process and minimizing the incidence of high-risk diseases in the elderly.

Thus, misclassifying an elderly person as a patient with CKD involves an unnecessary psychological burden for the patient and his family, as well as unnecessary medical care and increased financial expenses.

Conflicts of interest and sources of funding
The authors declare no conflict of interest.

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers may cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor may not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Editor-in-Chief. The Editor-in-Chief reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at: http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

– Accessible to the public at no charge;

– Searchable by standard, electronic (Internet-based) methods;

– Open to all prospective registrants free of charge or at minimal cost;

– Validates registered information;

– Identifies trials with a unique number; and

– Includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, a target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The Journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 200 words. Abstracts for original articles should be formatted as detailed in the word form. Titles must not be longer than 120 characters (including spaces). In every article, there must be three to ten pertinent keywords specific to the article yet reasonably common within the subject discipline.

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article. This should be cited as Rom. J. Mil. Med. (year); (vol): [issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related “miniseries” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this

avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are suggested to limit to 3000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Executive Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as ‘What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?’ Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate.

Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors’ revised ‘Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication, as presented at http://www.ICMJE.org/.

Spelling

The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster’s Collegiate Dictionary.

Units

All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations

Abbreviations should be used sparingly and only where they ease the reader’s task by reducing the repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: the title page; the main text file according to the word model.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author’s institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors’ industrial links and affiliations. In the case of clinical trials or an article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented according to the word model. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 200 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. If appropriate, divide the abstract with the headings: Background and Aim, Methods, Results, and Conclusions. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to ten keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine’s Medical Subject Headings (MeSH) browser – http://www.nlm.nih.gov/mesh/meshhhome.html.

Text

Authors should use the word form in editing the submitted material.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square parentheses in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or fewer; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

Use Index Medicus as the style guide for references and other journal abbreviations.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table and legend must be

understandable without reference to the text. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, •, ‣ should be used (in that order) and *, **, *** should be reserved for P-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication:

Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com. A cover letter containing an authorship statement should be included. The cover letter should include a statement covering each of the following areas:

– Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author. It is not accepted the idea of equal contribution.

– Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.

– A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

– For research involving pharmacological agents, devices, or medical technology, a clear Conflict of Interest statement about any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

– For clinical trials, these have been registered in a publically accessible database (see more under 'ETHICAL CONSIDERATIONS (Further Information)' later in these guidelines).

If the above items are not included in the cover letter, manuscripts cannot be sent for review. Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using the word model that is to be found on the web page (http://revistamedicinamilitara.ro/wpcontent/uploads/2022/07/Macheta-articole.docx).

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, high-resolution figures (at least 300 d.p.i.) saved as .eps, .jpg or .tif files are required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted Articles

Accepted Articles are published online after final acceptance, and appear in PDF format only.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing the proof of acceptance. It is therefore essential that a working e-mail address is provided for the corresponding author.

COPYRIGHT, LICENSING, AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is submitted.

Abstract: *Matrix metalloproteinases (MMPs) are a member of the protein family intimately associated with zinc-containing endopeptidases, which are the main proteases implicated in extracellular matrix (ECM) degradation. The high ability of MMPs in the degradation of extracellular proteins is an important event in many normal biological as well as pathologic processes, including tumor progression, tissue repair, wound healing, developmental morphogenesis, and inflammatory diseases. This review is focused on the description of the modulation mechanism of MMPs via oncoviruses. Up to now, a large number of oncogenic viruses have been detected and recognized as etiologic factors of multiple human cancers. Actually, by expression of several viral oncoproteins of tumorigenic viruses with the simple genetic system, we are able to deregulate or modulate the pathways of cell transformation procedure in malignancy. In brief, upregulated expression of MMPs genes by direct (through DNA binding) , as well as indirect interactions (by activating PI-3K/AKT, ERK/MAPK, IFN/JAK/STAT, JNK, NF-κB signaling pathways and/or immune response) with tumorigenic viruses, have a noticeable role in the proliferation of cells, as well as angiogenesis, mobility, EMT, invasiveness, and metastatic features. In fact, the growth of tumor-related researchers offers a future perspective for the efficiency of targeted, molecular-based therapies and its anticancer effects via diverse mechanisms such as the suppression of viral oncoproteins.*

Keywords: *Matrix Metalloproteinases (MMPs), Tumor Viruses, Tumor Progression*

INTRODUCTION

Matrix metalloproteinases (MMPs), form a family of zinc-dependent extracellular matrix (ECM) remodeling endopeptidase enzymes that play a role in a number of physiological processes, like the healing of wounds, organismal development, and effectors of immune responses, as well as in pathological conditions, like pulmonary dysfunctions, autoimmune diseases, and cancer [1,2]. To date, almost 25 various vertebrate MMPs have been recognized, including 23 members in humans [3]. Based on sequence homology and specificity for substrate, the MMPs family divides into six categories of stromelysins, collagenases, matrilysins, gelatinases, membrane-type as well as other non-classified MMPs [4]. Each of these groups has its subunits that perform unique functions [5]. Chemokines, cytokines, as well as growth factors, cell-to-to-cell adhesion molecules, and binding proteins, can be mentioned as other potential targets for MMP substrates [6]. The classification of MMPs is indicated in Table 1 shown [7-11]. Matrix metalloproteinase (MMPs) activity might be regulated at three transcription levels, production of enzymes like zymogens, which require activation, as well as co-expression of tissue inhibitors of metalloproteinases (TIMPs) [12,13]. MMPs transcription is perfectly controlled, and their expression level of them is low. TIMPs are endogenous suppressors of metalloproteinases that can inhibit the MMM's catalytic activity, therefore maintaining ECM homeostasis [14]. MMPs are produced in their inactive zymogenic forms (proenzymes or pro-MMPs), which are subsequently proteolytically activated by removing propeptides by other proteases [15]. The majority of MMPs are activated in the extracellular space via plasma, tissues, and microbial proteases. The rest of the activated MMPs like MT-MMPs, MMP-11, 23, and 28 possess a furin-dependent cleavage motif RXK/RR in the propeptide sequence, which are intracellularly activated via furin-like proteases of Golgi [16]. Any disruption in the regulation of MMPs modulatory mechanisms may associate with the progression of the disease in pathological conditions [12].

Table 1: Classification of the main members of the MMP family by chromosomal location and the group of substrates

MMP number	MMP subclass/ Family/Group	MMP name	Substrates	Chromosome
MMP-1	Collagenases	Interstitial collagenase	Collagens (I,II,III,VIII a X); gelatin; aggrecan; L-selectin; IL-1β proteoglycans, entactin; ovostatin; MMP-2; MMP-9	11q22-q23
MMP-2	Gelatinases	Gelatinase A	Collagens (I,IV,V,VII,X,XI a XIV); gelatin; elastin; fibronectin; aggrecan; MBP; osteonectin; laminin-1; MMP-1; MMP-9; MMP-13	16q13
MMP-3	Stromelysins	Stromelysin 1	Collagens (III,IV.V, a IX); gelatin; aggrecan; perlecan; decorin; laminin; elastin; casein; osteonectin; ovostatin; antactin; plasminogen; MBP; IL-1β; MMP-2/TIMP-2; MMP-7; MMP8; MMP-9; MMP-13	11q23
MMP-7	Matrilysins	Matrilysins	Collagens (IV a X); gelatin; aggrecan; decorin; fibronectin; laminin; entactin; elastin; casein; transferrin; plasminogen; MBP; β4-integrin; MMP-1; MMP-2; MMP-9; MMP-9/TIMP-1	11q21-q22
MMP-8	Collagenases	Neutrophil collagenase	Collagens (I,II,III,V,VII,VIII a X); gelatin; aggrecan; fibronectin	11q21-q22
MMP-9	Gelatinases	Gelatinase B	Collagens (IV,V,VII,X a XIV); gelatin; entactin; aggrecan; elastin; fibronectin; osteonectin; plasminogen; MBP; IL-1β	20q11.2-q13.1
MMP-10	Stromelysins	Stromelysin 2	Collagens (III-V); gelatin; casein; aggrecan; elastin; MMP-1; MMP-8	11q22.3-q23
MMP-11	Stromelysins	Stromelysin 3	Unknown (casein)	22q11.2
MMP-12	Elastase	Metalloelastase	Collagen IV; gelatin; elastin; casein; fibronectin; vitronectin; laminin; entactin; MBP; fibrinogen; fibrin; plasminogen	11q22.2-q22.3
MMP-13	Collagenases	Collagenase-3	Collagens (I,II,III,IV,IX,X,a XIV); gelatin; plasminogen; aggrecan; perlecan; fibronectin; osteonectin; MMP-9	11q22.3
MMP-14	Membrane-MMP	MT1-MMP	Collagens (I-III); gelatin; casein; fibronectin; laminin; vitronectin; entactin; proteoglycans; MMP-2; MMP-13	14q11-q12
MMP-15	Membrane-MMP	MT2-MMP	Fibronectin; entactin; laminin; perlecan; MMP-2	16q12.2-q21
MMP-16	Membrane-MMP	MT3-MMP	Collagen III; gelatin; casein; fibronectin; MMP-2	8q21
MMP-17	Membrane-MMP	MT4-MMP	Gelatin	12q24
MMP-18	Collagenases	Collagenase-4	Unknown	Unknown
MMP-19	Other	RASI-1	Gelatin; tenascin; fibronectin; collagen IV; laminin; entactin; fibrin/fibrinogen; aggrecan	12q14
MMP-20	Other	Enamelysin	Amelogrenein; aggrecan; COMP	11q22
MMP-23	Other	Unnamed	Amelogenin	11q22
MMP-24	Membrane-MMP	MT5-MMP	Pro-MMP 2	20q11.2
MMP-25	Membrane-MMP	MT6-MMP	Pro-gelatinase A; fibrin; fibronectin; collagen IV; gelatin	16p/3.3
MMP-26	Matrilysins	Endometase, matrilysin-2	Gelatin Iα; P1; fibrinogen; fibronectin; vitronectin; β-casein	Unknown

MMPs AND TUMOR PROGRESSION

Cancer is the second factor of death globally, which is estimated to account for 9.6 million deaths in 2018 [17]. Recent two decades of biomedical research have led to large amounts of information about the molecular events which occur during carcinogenesis as well as signaling pathways involved in the progression of cancer. Complex molecular mechanisms play different roles in the tumor cells and the tumor environment associated with this process [18]. Several interactions of tumor cells with the involved environment of the tumor are crucial for the pathological changes observed during the transformation of cells and carcinogenesis in the extracellular matrix (ECM), as well as cytokines, growth factors associated with ECM, along with neighboring cells (neutrophils, endothelial cells, mast cells, macrophages, fat cells, and pericytes) [19-21]. Different steps of cancer consisting of migration, attack, metastasis, and angiogenesis are in interaction with the neighboring microenvironment [22]. MMPs are the main molecules in these processes, and since they break down numerous cell adhesion molecules, indicating their roles in the regulation of cell-to-cell, and cell-ECM interactions [23,24]. Previous researchers have identified that MMPs play an essential role in all phases of tumor maintenance and growth, including invasiveness, migration of tumor cells, evasion from apoptosis as well as immune surveillance, angiogenesis, and metastasis, so that all these major stages may be modulated by MMPs [25].

Interferon, interleukins, growth, factors, and extracellular MMP inducers secreted from tumor cells in a paracrine, manner stimulating adjacent host cells to generate the required MMPs. MMPs produced by normal cells can be bound and used on the surface of tumor cells [26]. MMPs gene expression and its activity increase in many types of cancers in humans. And this increased expression causes an increase in tumor size, invasion, and decreased survival [27]. Thus, MMPs are used as a novel and capable therapeutic target in different types and cancer phases [28]. MMPs use their proteolytic function to remove physical barriers, developing angiogenesis and tumor metastasis [29]. Tumor development and angiogenesis depend on the facilitated accessibility of signaling molecules. For example, cytokines and growth factors by MMPs enhance by making them available for tumor cells and their microenvironment [18]. This process is performed by releasing these factors from the ECM (VEGF, IGF, and bFGF) or via secreting them from the surface of the cell (HB-EGF, EGF, TGF-a) [4]. The release of endogenous angiogenesis suppressers can regulate angiogenesis perfectly, for instance, angiogenesis inhibitors like tumstatin, endostatin, angiostatin, and endorepellin [30]. Disruptions in the regulation of cell-cell and cell-ECM interactions by MMPs during the processing of E-cadherin and integrins, respectively, affect both cell phenotype (EMT) as well as increasing cell migration [31,32]. Almost all members of the MMP family have been reported to be dysregulated in human tumors, although MMPs such as MMP-1, -2, -7, -9, -13, and 14 are more important [33]. We have demonstrated the most noticeable MMPs, which are related to the phases of tumor growth, biological effects, and their consequences in Table 2.

Table 2: Key MMPs in relation to the stages of cancer progression, biological effect, and consequences

Function	MMP	Biological effect	Consequence	Reference
Cancer cell invasion	MT1-MMP, MMP-2 and MMP-9	Proteolytic	Breakdown physical barriers	[144]
Cancer cell proliferation	MMP-1, -2, -3, -7, -9, -11, -19	Cleavage of IGF binding proteins, Shedding of membrane, anchored ligands of EGFR, including HB-EGF, TGF-a and amphiregulin, Activation of TGF-β, Shedding of HB-EGF	Proliferation	[145-147] [148] [149] [150]
Cancer cell apoptosis	MMP-7 Several MMPs	Cleaving the Fas ligand Indirect activation of the serine/serine/threonine Akt ⁄ protein kinase B through the signaling cascades of EGFR and IGFR	Anti-apoptotic	[151] [147, 152]
Tumor angiogenesis	MMP-2, -9 MMP-3, -10, -11 MMP-1, -8, -13	Degradation of COL-IV, perlecan; release of VEGF and bFGF, respectively Degradation of COL-IV, COL-XVIII, perlecan; generation of tumstatin, endostatin, angiostatin and endorepellin, respectively	Upregulation of angiogenesis Downregulation of angiogenesis	[153, 154] [4, 155]
Cell adhesion, migration, and EMT	MMP-2 MT1-MMP MMPs MMP-2, -3, -9, -13, -14 MMP-1 and -7 MMP-28	Degradation of COL-IV; generation of cryptic peptides Degradation of laminin-5; generation of cryptic peptides Integrins as substrates Overexpression this MMPs associated with EMT, a highly conserved and fundamental process of morphological transition By cleavage E-cadherincontribute to morphological transition Proteolytic activation of TGF-β	Promote migration Induction of EMT; cell migration Powerful inducer of EMT, leading to cell migration	[156, 157] [158] [159] [160] [161]
Immune surveillance	MMP-9 MMP-9, -2, -14 MMP-7, -11, -1, -8, -3 MMP-7, -8	Cleavage of IL-2R alpha Release active TGF- β Release of a1-proteinase inhibitor Cleave several members of the CC (β-chemokine) and CXC (α-chemokine) chemokine subfamilies or to regulate their mobilization	Repress T-lymphocyte proliferation Abolish T-lymphocyte reaction against cancer cells Decrease cancer cell sensitivity to NK cells Affecting leukocyte infiltration and migration	[162] [163] [164] [165, 166]

ONCOVIRUSES

Approximately 20% of all human malignancies worldwide are associated with viruses [34]. Seven viruses have been implicated as oncogenic, including HPV, EBV, HCV, HBV, Kaposi's sarcoma-associated herpesvirus (KSHV), HTLV-1, and Merkel cell polyomavirus (MCV), which have been reported to be etiologically implicated in the maintenance and progression of human cancers [35]. However, viral oncogenesis processes are a complex process, with induction of chronic inflammation conditions, disruption of cellular DNA repair mechanisms, interrupting host genetic and epigenetic integrity, and homeostasis, viral infection may result in genome variation and cell cycle deregulation. Viral ‘oncoproteins’ are capable of modulating or deregulating cellular signaling pathways, making changes in the expression of genes and microRNAs in either transcription or post-transcription, and disrupting tumor suppressor factors and proteins, which regulate cell polarity, immune response, signal transduction, and cell apoptosis. Genetic and epigenetic modifications caused via oncoviruses may be resulting in the morphology and variation of cancer stem cells, which are essential for the primary initiation, development, migration, invasiveness, and chemotherapy resistance of tumors. These molecular events underlying the interactions between oncoviruses that use specific cellular genes and cellular signaling pathways are important issues to research efforts [36-38]. MMPs have several specific biological actions in every cancer phase, from the beginning to the extension of pertinent metastases. Accordingly, this review’s focus is on characterizing the mechanism of modulation or deregulation of MMPs by oncoviruses.

INTERACTION BETWEEN ONCOVIRUSES AND MMPs

Epstein-Barr virus

Epstein-Barr virus (EBV) is a linear dsDNA virus that belongs to the human gamma-herpesvirus family, playing a role in different B-cells lymphomas, including Hodgkin’s lymphoma, Burkitt’s lymphoma, post-transplant lymphoproliferative disorders, as well as other tumors like T-cell non-Hodgkin lymphomas and nasopharyngeal carcinoma [39]. In tumors associated with EBV, the virus leads to a latent infection expressing only a subset of 12 latent viral transcripts, two early RNAs (EBERs), three latent membrane proteins (LMPs), six nuclear antigens (EBNAs), and BARF transcripts. Out of these genes, EBNA1, EBNA-2, EBNA-3A, EBNA-3C, EBNA-LP, and LMP1 enable the virus to control a number of cellular signaling pathways associated with oncogenesis [40,41]. EBV LMP1 increases MMP-9 expression by recruitment of Sp-1, AP-1, and NF-kappa B transcription factors on MMP-9 promoter that is related to invasiveness and metastasis in EBV-associated NPC [42]. Previous research demonstrated that C-terminal activation regions 1 and 2 (CTAR-1 and CTAR-2), two crucial signaling domains within the carboxy terminus of LMP1, might activate the MMP-9 promoter and stimulate MMP-9 activity [43]. TANG Jian showed EBV-induced MMP-9 upregulation correlates with lymph node metastasis and clinical stage in NPC tumors [44]. Lee demonstrated that upregulation of MMP1 and MMP3 expression in LMP1-positive NPC tumors led to the enhancement of invasiveness in NPC cells [45]. BZLF1 (also known as Zta) is one of the critical inducers of EBV lytic cycle alteration and has been reported to trigger metastasis in epithelial cells [46, 47]. In vitro studies demonstrated that Zta stimulates MMP3 and MMP9 expression in epithelial cells derived from NPC tumors. Zta can activate the MMP3 promoter by AP-1 elements, and its DNA-binding domain is necessary for the process of promoter binding and MMP3 stimulation. Zta-enhanced cell migration requires MMP3 but not MMP9. Zta-elevated cell migration needs MMP3, but not MMP9. Therefore, the expression of both MMP3 and MMP9 is important for the co-expression of the two MMPs (MMP3 and MMP9) induced by Zta, which simultaneously promotes cell invasiveness of epithelial cells differentiated from NPC tumor [48]. Moreover, Zta protein via binding AP-1 site of its promoter increases TIMP-1 expression in EBV-infected B-cells as well as EBV-immortalized lymphoblastoid cell lines (LCLs). Upregulation of TIMP-1 expression through Zta enhances the maintenance of EBV-infected B-cells and promotes the progression of EBV-associated cancer [49]. EBNA3C regulates the transcription of numerous viral as well as cellular genes important for the process of immortalization by EBV in primary B-lymphocytes [50]. Nm23-H1 is a well-known metastasis inhibitor, and its low expression is correlated with metastatic tumor capability in different types of human carcinoma [51]. In vitro research showed the interaction of EBNA3C with Nm23-H1 leads to the translocation of Nm23-H1 to the nucleus and inhibits the antimotility effect. However, studies have shown that this interaction also can increase transcriptional activity on a related promoter of the target gene [52]. Interaction between EBNA3C and Nm23-H1 upregulates the expression of MMP-9 by binding the transcription factors AP-1 and NF-kB on its promoter in B-cells that were isolated from Burkitt’s lymphoma [53]. LMP2A promotes cell transformation, migration, and invasion by affecting host cellular signaling pathways, mainly by its N-terminus, intracellular domain, which consists of an immunoreceptor tyrosine-based activation motif (ITAM), a YEEA motif, and two PPPPY (PY) motif [54,55]. LMP2A promotes invasion of NPC cells by the PY motif via stimulation of extracellular signal-regulated kinase (ERK)-1/2 as well as the downstream transcription factor Fra-1, therefore leading to upregulation of MMP9 expression [56]. WW domain-containing oxidoreductase WOX1, also called WWOX or FOR, is a candidate tumor inhibitor encoded by the human fragile WWOX gene, related to several signaling pathways modulating embryonic development, metabolism, cell proliferation, and apoptosis [53]. The function of WOX1 in cancer suppression is commonly used by stimulating apoptosis and sequestering some oncoproteins [57,58]. According to a previous study, the interaction of the tyrosine residue 33 of WOX1 and the PY motif of LMP2A is needed for the LMP2A-induced ERK1/2-Fra-1-MMP9 pathway in NPC cells (Figure 1) [59]. Two SNPs (rs8113877T>G or rs17576A>G) of MMP-9 in ab_EBV positive individuals were associated with more possibility of progression to chronic lymphocytic leukemia in contrast to those individuals who were negative [60]. In summary, the upregulation of MMPs by EBV plays a significant role in EBV-triggered metastasis.

Human papillomavirus

Human papillomaviruses (HPVs), namely double-stranded DNA viruses, are recognized as one of the main agents that relate to the progression of numerous cancers such as head and neck, cervix, vagina, vulva, anal and penile carcinomas [61]. Continuing infection with high-risk human papillomavirus (HPV) types, especially HPV type 16 or 18, is essential for the development of a cancer precursor lesion and invasive cervical cancer, which is identified through deregulated and high-level expression of HPV early genes (E6 and E7) [62]. The high-risk HPV E6 and E7 oncoproteins result in transformation by a disruption in the activity of cellular tumor suppressor proteins p53 and RB, respectively, and several cellular proteins [63,64]. Induction of MT1-MMP expression in HaCaT cells, an immortalized human keratinocyte line, by the E7 protein of high-risk HPV types 16 and 8 contributes to cellular proliferation, angiogenesis, and, malignant progression, for the invasion of HPV-positive tumor cells [65]. In human keratinocytes and organotypic skin cultures, HPV8 E2 protein overexpresses the expression of MMP-9 by direct activation of its promoter, resulting in increased squamous fragility involved in facilitating viral escape [66]. A recent study demonstrated that HPV-16 E6/E7 oncoproteins cause upregulation of MT1-MMP, MMP-2, and MMP-9 to promote cervical cancer cells [67]. Previous studies reported that HPV 16 infection might lead to lung tumor cells through increasing in interleukin-17 (IL-17) expression. IL-17 along with its downstream signaling mediator, interleukin-8 (IL-8), play an efficient role in tumor angiogenesis and metastasis by modulation of various pro-angiogenic factors [68]. Induction of IL-8 by HPV upregulates the expression of MMP-2 and MMP-9 in lung adenocarcinoma that correlated with progressive mechanisms of growth, and metastatic and angiogenic characteristics [69]. HPV-16 E6/E7 overexpressed the expression of MT1-MMP and MMP-2, which are correlated with increased cell invasion in cervical cancer [70]. According to recent research (Haukioja), low salivary levels of MMP-8 are due to continued oral HPV infection, which appears like a failure of the anti-inflammatory defense of the oral mucosa to allow an incident oral HPV infection to become a chronic infection [71]. Common skin extract immunoblots and zymographic analysis revealed increased expression of MMP-9, MMP-13, and MT1-MMP in HPV8-positive mice rather than HPV8-negative mice, which are involved in the development of HPV8-induced cutaneous tumors (Figure 2) [72]. Singh et al. have shown that SNPs -1306CC (rs243865: C>T) in the promoter of the MMP2 gene, enhanced transcription and enzymatic activity of the MMP-2 gene is associated with the incidence possibility of cervical cancer. A significant relationship between the −1306CC genotype and HPV infection in increasing the risk of cervical cancer was observed [73].

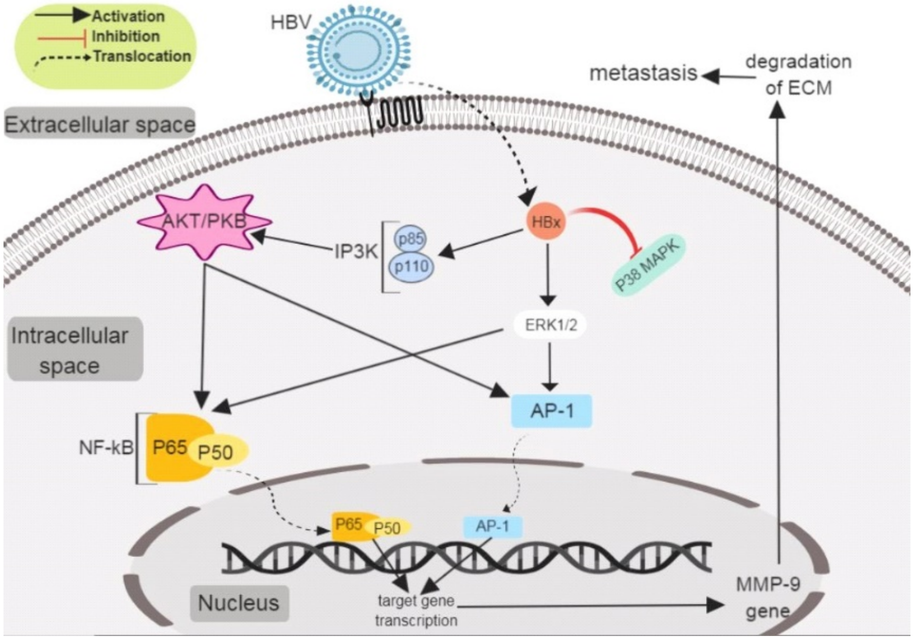
HBV

Chronic hepatitis B (CHB), an important agent responsible for liver cirrhosis and hepatocellular carcinoma, is among the primary health problems of the world [74,75]. HBV transactivator protein (HBx) enables the invasive capacity of the virus, which is mediated by increased the expression of membrane-type one matrix metalloproteinase (MT1-MMP) that subsequently activates matrix metalloproteinase-2. HBx is able to induce both MT1-MMP expression and cell invasion through dependence on cyclooxygenase-2 (COX-2) activity. Furthermore, HBx increases COX-2 expression through the activation of COX-2 gene promoter transcription in a nuclear factor of an activated T-cell-dependent (NF-AT–dependent) manner. These data indicated the capacity of HBx to augment tumor cell invasion by a mechanism consisting of MT1-MMP and COX-2 upregulation and led to new insights into HBx protein mechanism of action, its involvement in tumor metastasis and hepatocellular carcinoma resulting from intrahepatic metastasis to HBx protein expression following establishment of tumor [76]. HBx protein plays a crucial role in the progression of hepatocellular carcinoma (HCC). HBx is often the only HBV protein that would be detected in hepatic tumor cells, which enhances tumor cell invasion and metastasis. HBx, by inducing the PI-3K/AKT and ERK pathways except for the P38 MAPK pathway, leads to the activation of NF-kB and AP-1 transcription factors. HBx triggers the translocation of NF-kB and AP-1 into the nucleus, leading to increasing MMP-9 expression. Thus, HBx modulates the transcriptional function of MMP-9 that is essential to the incursion and metastasis of tumors through PI-3 K/AKT and

ERK pathways. These findings suggest that HBx could induce MMP-9 and, in turn, in the invasion and metastasis of cancer, by activating ERK and PI-3K signaling pathways (Figure 3) [77].

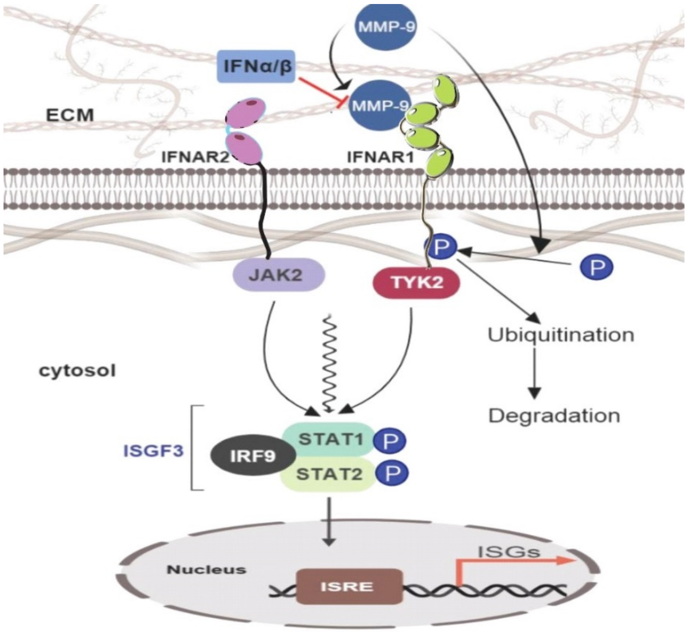
Figure 3: Molecular mechanism of HBX-activated MMP-9 expression. HBx induces PI-3K/AKT and ERK pathways but not the p38 MAPK pathway. This process leads to the stimulation of NF-kB and AP-1 transcription factors. Translocation of NF-kB and AP-1 activated by HBx into the nucleus leads to an increase of MMP-9 expression. Therefore, HBx via regulation of transcriptional activation of MMP-9, plays an important role in the invasion and metastasis of tumors via PI-3K/AKT and ERK pathways



Genes that were defined to be modulated in the presence of HBx include those genes involved in signal transduction, cell cycle, cytokine production, metabolism, apoptosis, cell adhesion, and oncogenesis. The functions of other less-defined genes also were affected. Transactivation by HBx upregulates the translation, transcription, and release of matrix metalloproteinase-3 (MMP-3), which manifests as a cell migratory phenotype. This effect of HBx was suppressed in the presence of an MMP-3-specific peptide inhibitor. HBx applies selective control of transcription in hepatoma cells as well as inducing cell migration via activation of MMP-3. Therefore, by upregulation of MMPs, HBx increases the invasion of tumor cells and the destruction of the extracellular matrix that is reported to increased cell migration [78]. The progression of tumors tightly depends on a permissive microenvironment that is highly correlated with the destiny of tumor cells. The normal structure of ECM is of high importance in the modulation of cell growth. For invasiveness, cancer cells must overwhelm the mechanical barriers caused by the ECM. It has been demonstrated which conformational changes in the ECM by MMPs have a noticeable role in the mobility and spread of tumor cells, resulting in invasion and metastasis. The activation of MMP induced by HBx signifies a role of HBx protein in the development of HCC metastasis. However, HBx is demonstrated to relieve transcriptional stimulation activity, it is not defined in what way HBx induces the expression of MT1-MMP [79,80]. HBV replication is assisted by MMP-9 through repression of IFN/JAK/STAT signaling as well as IFNAR1 function. Thus, these outcomes have discovered a novel role for MMP-9 in viral replication, revealing a new mechanism by which HBV escapes host immunity to maintain persistent infection. Indeed, there is a positive feedback loop between the injection of HBV and the production of MMP-9. Firstly, HBV activates MMP-9 production in PBMCs and macrophages. Subsequently, HBV replication would be facilitated by MMP-9 through repressing IFN/JAK/STAT signaling, interacting with IFNAR1 to prevent its binding to IFN-α and promoting the ubiquitination phosphorylation, degradation of IFNAR1 and ISRE, subcellular distribution, and interferon-stimulated response element. Thus, MMP-9 would benefit HBV by blocking innate immunity to launch or maintain chronic infection (Figure 4) [81].

In hepatitis B infection, apoptosis of liver cells that is induced by varying degrees of inflammation plays an essential role in the outcome of CHB [82]. The MMP-9 expression level is directly related to TNF-α and IL-6. Because IL-6 and TNF-α can regulate MMP-9 activity in a concentration- and time-dependent mode, overexpression of MMP-9 can degrade ECM to destroy the basement membrane and lead to disorganized and loose tissue structures, leading to further penetration of TNF-α and IL-6. These factors can interact with each other and create a vicious cycle, resulting in pathological changes in the liver. In conclusion, the MMP-9 level is increased remarkably in patients with varying degrees of CHB, it would be important in the pathological progress of the liver, and it has a close correlation with inflammation, which can provide a theoretical basis for clinical treatment [83].

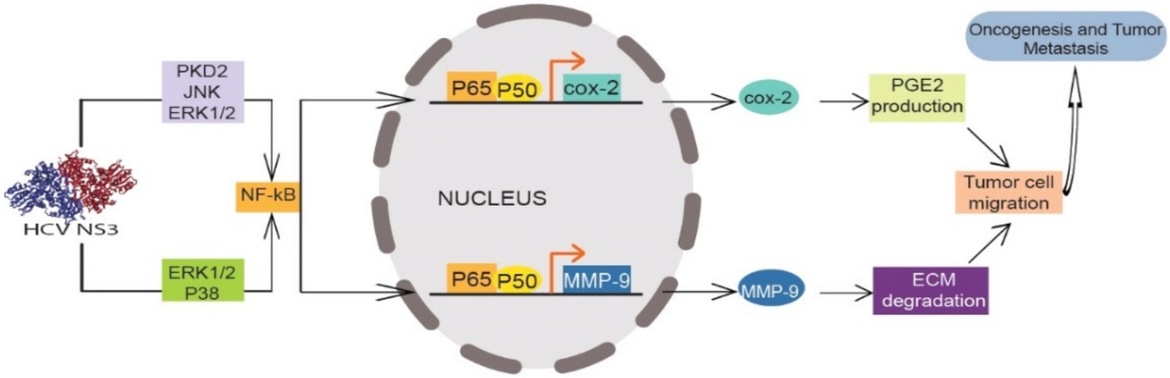
Figure 4: MMP-9 assists HBV replication by suppressing IFN/JAK/STAT signaling and IFNAR1. Indeed, HBV induces MMP-9 in infected patients and in HBV-stimulated leukocytes. Then, MMP-9 comforts HBV replication through repressing IFN/JAK/STAT signaling, interacting with IFNAR1 to block its binding to IFN-α, and promoting the phosphorylation, ubiquitination, subcellular distribution, and degradation of IFNAR1



HCV

Hepatic inflammation, cirrhosis, developing liver fibrosis, and hepatocellular carcinoma (HCC) are common problems in HCV patients [84,85]. In the liver, the main reason for fibrogenesis is pathological repletion of the extracellular matrix (ECM), which leads to an imbalance in the rate of enhanced matrix synthesis to reduce the degradation of connective tissue proteins that can be controlled by matrix metalloproteinases (MMPs). Recent studies showed that increasing levels of hepatic gelatinases, including MMP-9, and MMP-2, are related to the progression of HCC and the fibrotic index of chronic HCV patients [86,87]. The disparity between matrix metalloproteinases (MMPs) and tissue suppressors of matrix metalloproteinases (TIMPs) is remarked to be a significant index of degradation of the extracellular matrix. MMPs are members of gene families that can degrade collagen and play an essential role in the natural mechanism of tissue repair in pathological states, including liver fibrosis. Thus, an increase of the MMP-1/TIMP-1 ratio by IFN treatment can relieve liver fibrosis of chronic hepatitis C that demonstrates the anti-fibro genetic effect of IFN on the factors modulating hepatic fibrosis [88]. During chronic liver harm, activated hepatic stellate cells (HSC) turned backward into myofibroblast-like cells and proliferated. This stage is an important factor in the creation of fibrosis and subsequent cirrhosis [89]. HSCs are considered important sources of fibrillar as well as nonfibrillar collagens of the liver, matrix-degrading proteases (MMPs), and their specific blockers (TIMPs). Briefly, recent studies on patients with chronic hepatitis C reported important variations in hepatic TIMP and MMP expression. It is likely that TIMP expression was affected via the inflammatory conditions of the disease, which can reflect the effects of the disease. Promoted fibrosis enhances the expression of MMP-7 and MMP-2 and provides a condition for the destruction assessment of connective tissue [86]. The primary activity in the biosynthesis of different prostaglandins (PG) and thromboxanes catalyzes via cyclooxygenases [90,91]. There are two cyclooxygenases (COX) isoforms: COX-1 is basically expressed in several cell types and is the main factor in the homeostatic activity of PG, while COX-2 is triggered by different proinflammatory stimuli, including lipopolysaccharide (LPS) and cytokines [92-94]. COX-2 is involved in fibrogenesis, inflammation, and carcinogenesis [95-97]. Therefore, different researchers reported that increased COX-2 expression and PG production might be associated with liver dysfunction and tumorigenesis in various animal models [98-100], in addition to fibrosis and hepatocellular carcinoma (HCC) among humans [101,102]. HCV core and NS5A proteins, both alone and in association with the impact of endotoxin and proinflammatory cytokines, are capable of regulating the expression of COX-2 and MMP-9 genes through chronic HCV infection. Therefore, this mechanism may be considered evidence for this process that chronic HCV infection may result in liver fibrosis. Thus, it seems reasonable that much PGs generated in hepatocytes via the correlated effect of HCV proteins in addition to inflammatory factors may affect neighboring liver cells by autocrine and/or paracrine pathways, therefore participating in hepatocarcinogenesis [103]. The E2 envelope glycoprotein of the hepatitis C virus (HCV) is an important modulator of HCV interaction with cell surface receptors. E2 interacts with an extracellular loop of human CD81; it's a receptor expressed on various cell types such as hepatocytes and B-cells. CD81 on the cell surface is expressed in human hepatic stellate cells (HSC) at a high level, Matrix metalloproteinase-2 (MMP-2; gelatinase A), an important enzyme responsible for the degradation of the normal hepatic extracellular matrix, upregulates subsequently after binding E2 toCD81. Furthermore, E2/CD81 interaction in human HSC causes an increasing amount of MMP-2 via increasing the binding activity of activator protein-2/DNA via ERK/MAPK phosphorylation. Increased degradation of the hepatic extracellular matrix in HCV-concentrated regions may be associated with inflammatory as well as parenchymal damage [104]. HCV replication may be regulated by signal cascades, cellular factors, and viral proteins [105-108]. The HCV nonstructural protein 3 (NS3) has a serine protease required for the synthesis of viral protein and helicase activity needed for viral replication [109,110]. NS3 also is a major protein in modulating cell proliferation, indicating its role in carcinogenesis [111,112]. HCV NS3 protein facilitates tumor cell invasion in two ways. Firstly, NS3 induces several signaling pathways like protein kinase D2 (PKD2), JNK, and ERK1/2 to modulate the transcription factor NF-κB, and subsequently, it regulates the expression of COX-2 [113], and COX-2, in turn, activates MMP-9 expression. Secondly, NS3 induces the ERK1/2–p38 signal pathway to modulate the activity of NF-κB, which triggers the translocation of NF-κB to the nucleus and binding of NF-κB to MMP-9 promoter, which consequently upregulates MMP-9 expression. MMP-9 (an important enzyme in degrading the extracellular matrix), and COX-2 (the main enzyme in prostaglandin E2 production) exert key roles in tumor invasion and tumorigenesis. Therefore, NS3 enhanced tumor cell metastasis by MMP-9 and COX-2, leading to tumorigenesis (Figure 5) [114]. The MMP2, MMP9, and TNF-α levels have an effective increase in chronic HCV patients. However, no considerable correlation has been reported in the levels of MMPs and TNF-α between fibrotic and cirrhotic cases. In consequence, MMP2, MMP9, and TNF-α revealed high reproduction capacity in distinct patients afflicted with liver fibrosis (F1–F4) compared to the control group. In contrast, MMP9, MMP2, and TNF-α were not distinguishable factors for liver fibrosis in patients with chronic HCV. Therefore it is likely that they would be used as prognostic markers for liver fibrosis [115].

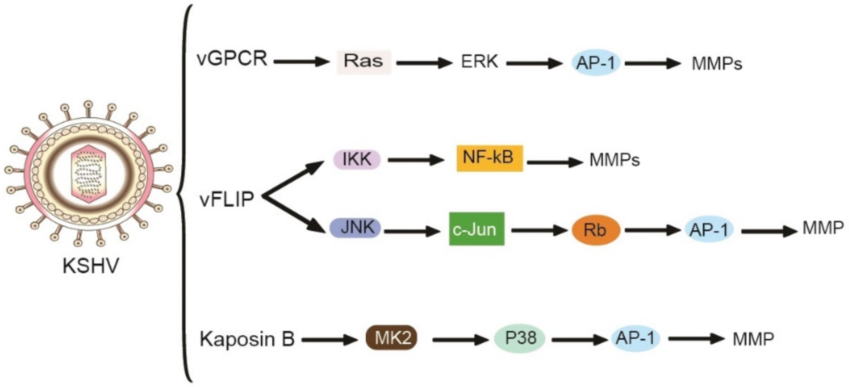
Figure 5: The mechanism of hepatoma cell invasion by HCV NS3 protein. First, NS3 activates multiple signaling components such as protein kinase D2 (PKD2), JNK, and ERK1/2 to regulate the activity of transcription factor NF-κB, which in turn regulates the expression of COX-2, and then COX-2 activates MMP-9 expression. Second, NS3 activates ERK1/2–p38 signaling pathway to regulate NF-κB activity, stimulates the translocation of NF-κB from the cytosol to the nucleus and the binding of NF-κB to the MMP-9 promoter, and thus activate MMP-9 expression.Thus, NS3 enhances tumor cell migration through COX-2 and MMP-9, resulting in oncogenesis or tumorigenesis



KSHV

Human herpesvirus-8 (HHV-8) or Kaposi sarcoma-associated herpesvirus (HHV-8 /KSHV) is a ds DNA virus with 165 kb in length. The HHV-8 life cycle consists of two states, lytic replication, and a latent phase. After primary infection, HHV-8 uses the cellular machinery of the host for replication and is subsequently observed in a latent phase as an episome. Like all herpesviruses, the B lymphocyte is the primary source of HHV-8 latency. The second sites for viral latency are endothelial cells, but these cells are the first infected cells in Kaposi sarcoma (KS). During latency, HHV-8 can regulate host cellular signaling pathways by different cellular mechanisms. Latent proteins, which include viral Cyclin a (v-Cyclin), LANA, kaposin, viral FLICE inhibitory protein (v-FLIP), and several miRNAs contribute to the pathogenesis of malignancies associated with HHV-8 [116]. HHV-8 has been identified in a Kaposi sarcoma lesion in an AIDS patient in 1994. This virus was reported to be associated with many B cell lymphoproliferative disorders (LPDs) such as posttransplant and germinotropic LPDs, multicentric Castleman disease (MCD), as well as primary effusion lymphoma (PEL) [117]. MMPs possibly associate with the mechanism of invasive KS growth and can be a proper target for effective therapeutic measures [118]. Developing KS lesional cells express gelatinases (MMP-2, MMP-9), stromelysin-1 (MMP-3), matrilysin (MMP-7), and collagenase (MMP-1, MMP-13) [119]. Cheng F. et al. demonstrated KSHV induces endothelial-to-mesenchymal transition (EMT). EMT was triggered by the viral proteins vGPCR and vFLIP via activation of the Notch pathway, which leads to a gain of membrane-type-1 matrix metalloproteinase (MT1-MMP) (Figure 6) [120]. The transcription factor PROX1 expression was recently investigated in KS. PROX1 binds the MMP14 promoter to repress its transcription. PROX1 negatively regulates MMP14 in normal tissues. Silvia Gramolelli et al. revealed that infection of lymphatic endothelial cells (LECs) with KSHV decreases PROX1 expression [121].

Figure 6: Schematic model of deregulation of MMPs by KSHV virus



Human T-cell lymphotropic virus type I (HTLV-I)

HTLV1 is a member of the retroviridae family, which is an etiologic factor of Adult T-cell Leukemia (ATL).ATL is a malignancy responsible for the extremely aggressive proliferation of CD4+ cells with no known cure [122]. ATL commonly originates from an infection that is acquired in early life [123]. Also, besides ATL, other manifestations of infiltrated T-cells, matrix metalloproteinases (MMPs), and cytokines of viral infection are Sjogren syndrome with an inflammatory appearance and HAM/TSP associated with neurological symptoms and incomplete paralysis of limbs [124-126]. The 3’ end of the genome (pX region) encodes some specific genes, including Rex, Tax, p12, p13, p30, and HTLV-1 bZIP factor (HBZ) [127,128]. HTLV-1 encodes two important genes, basic leucine zipper factor (HBZ), and tax, that are recognized to exert key roles in the infectivity of HTLV-1, survival, and growth of leukemic cells. Unlike HTLV-1 tax, HBZ escapes the antiviral response and is not detectable via the immune system. HTLV-1 provirus pX region encodes HBZ protein and in contrast to Tax, expressed in 100% of ATLL cells [123,129,130]. Although the proliferation of T cells is increased by HBZ, its function is interestingly antagonist to many tumorigenic activities of tax, such as activation of classical signaling pathways such as NFAT, AP-1, CREB, and NF-κB. Tax Repression through HBZ provides a condition for HTLV-1 to develop ATL by evading the immune system [123,131]. Tax may interact with cellular factors including AP-1, CBP/p300, CREB/ATF, and NF-κB. Both HTLV-1-replication and T-cell proliferation are generally enhanced by activating of IκB kinase (IKK)-NF-κB that is stimulated by viral Tax oncoproteins. Viral transactivator Tax is a presumed E3 ubiquitin ligase that is unitedly related with UbcH7, UhcH5c, and UbcH2 and is responsible for direct activation of IKK via binding to the NEMO subunit [132,133]. Bazarbachi et al. proved the interaction of HTLV-I-transformed cells in relation to endothelial cells triggers the gelatinase activity of MMP-9 and MMP-2 in endothelial cells and decreases the tissue blocker of MMP. In a study by Szymocha et al. on infected astrocytes (T cells) with HTLV-1, contact with T cells is the factor that the astrocyte obtains a typical phenotype of gliosis and causes the release of proinflammatory cytokines (i.e. IL-1 α, IL-6, TNF-α) and matrix metalloproteinases (MMP-3, MMP-9). The high expression of MMPs and their endogenous suppressors (TIMP-3 and TIMP-1) cause MMP/TIMP imbalance. It changes the extracellular matrix [134]. Giraudon et al. showed cytokines secreted by infected glial cells with HTLV-1 are responsible for increasing the expression of TIMP-3, and MMP-3, MMP-9, while MMP-2, TIMP-1, and TIMP-2 remained stable (Figure 7) [135].

MATRIX METALLOPROTEINASE INHIBITORS

Nowadays, MMPS targeting suppression of the activity of MMPs in the extracellular matrix as a novel anticancer strategy could be reconsidered. TIMPs, which are natural inhibitors of MMPs, at first, were the compounds to be developed for medical research. Hypothetically, TIMPs with potent inhibitory activity specifically can suppress the function of some MMPs which could lead to a useful therapeutic effect. However, their clinical application is still hampered by the absence of an efficient gene delivery style that has restricted the clinical use of this method [136]. Nevertheless, the progress of several types of natural synthetic suppressors of MMPs has been completely adopted and broadly investigated in clinical trials and researched in various cancers during the past decade (Table 3). Generally, synthetic suppressors of MMPs divide into three distinct pharmacologic groups including collagen non-peptidomimetics and peptidomimetics, tetracycline derivatives, and bisphosphonates [137].

THE RELATION BETWEEN INHIBITING OF MAJOR SIGNALING PATHWAYS BY MMP INHIBITORS AND ONCOVIRUSES

As previously mentioned, in HBV infection, HBx controls the transcription induction of MMP-9 which plays a key role in migration as well as metastasis of the tumor via PI-3 K/AKT and ERK pathways. Therefore, these data show that HBx plays a major role in inducing MMP-9 and, in turn, in the invasion and metastasis of cancer via activating ERK and PI-3K signaling pathways [77]. On the other hand, all the findings of one study already implied that 3-azidoWA suppresses 3-azidoWA-mediated MMP-2 expression through the attenuation of internal phospho-ERK as well as phospho-Akt expression in a dose-dependent condition that may have a significant role in the prevention of mouse angiogenesis as a natural inhibitor [138].

Table 3: An overview of the mechanisms deregulation MMPs by oncoviruses

Virus	Viral Factor	Number MMP	Mechanism/Effect	References
EBV	LMP1	MMP-9	Enhanced MMP-9 expression through induction of the MMP9 promoter by recruitment transcription factors AP-1, Sp-1, and NF-kappa B on MMP-9 promoter	[42]
	LMP1	MMP-1, MMP3	Upregulated MMP-1 and MMP-3 expression in NPC tumors	[45]
		MMP-9	Upregulated MMP-9 expression correlation with lymph nodes metastasis and clinical stage	[44]
	Zta	MMP-9, MMP-3	Overexpressed MMP-9 and MMP-3 expression in epithelial cells derived from NPC tumor	[48]
	EBNA3C	MMP-9	The interaction between EBNA3C and Nm23-H1 upregulated expression of MMP-9	[53]
	LMP2A	MMP-9	Upregulated MMP-9 expression by activation of extracellular signal-regulated kinase (ERK)-1/2 and a downstream transcription factor Fra-1	[56]
	Zta		Zta protein also up-regulated TIMP-1 gene expression in EBV-infected B cells and EBV-immortalized LCLs	[49]
HPV	E7	MT-1 MMP	E7 protein of the high-risk HPV types 16 and 8 lead to the induction of MT-1 MMP in in HaCaT cells	[65]
	E2	MMP-9	Increases the expression of MMP-9 in human keratinocytes and organotypic skin cultures	[66]
	E6/E7	MT1-MMP, MMP-2 and MMP-9	Upregulated expression of MT1-MMP, MMP-2 and MMP-9 in cervical cancer	[67]
		MMP-2, MMP-9	Up-Regulates MMP-2 and MMP-9 Expression and Activity by Inducing Interleukin-8 in Lung Adenocarcinomas	[69]
		MMP-8	Persistent oral HPV infection was associated with a low salivary MMP-8 concentration	[71]
		MMP-2, MMP-9, MMP-13 and MT1-MMP	Increased expression of MMP-9, MMP-13 and MT1-MMP in HPV8-positive mice than HPV8-negative animals	[72]
		MMP-2	A significant relationship was observed between the −1306C>T functional polymorphism in MMP-2 gene and HPV infection in increasing the cervical cancer risk	[73]
HBV	HBX	MT1-MMP, MMP-2	Up-regulated MT1-MMP expression by cyclooxygenase-2 (COX-2) activity and activates MMP-2	[76]
	HBX	MMP-9	Increased expression and regulate the transcriptional activaton of MMP-9 by activation of ERK and PI-3K signal pathways	[77]
	HBX	MMP-3	Up-regulated thetranscription,translationandsecretionofMMP-3	[78]
HCV	CORE AND NS5A	MMP-9	Up-regulated expression of MMP-9 with the synergistic effect of endotoxin and proinflammatory cytokines during chronic HCV infection	[103]
	E2	MMP-2	Up-regulation of MMP-2 by interaction between E2 and CD81and E2/CD81 interaction induced the up-regulation of MMP-2 by increasing activator protein-2/DNA binding activity via ERK/MAPK phosphorylation	[104]
	NS3	MMP-9	Activates MMP-9 expression by activates PKD2, JNK, and ERK1/2 to regulate NF-κB which regulates COX-2 expression , finally cox-2 activates mmp-9 expression	[114]
			Activates ERK1/2–p38 signal pathway to regulate NF-κB activity, stimulates the translocation of NF-κB from cytosol to the nucleus and the binding of NF-κB to the MMP-9 promoter	
KSHV	vGPCR and vFLIP	MT1-MMP	Increases of MT-MMP by induced EMT through activation of Notch pathway, leading to gain of MT1-MMP	[120]
		MMP-14	KSHV reduced prox-1 expression(Prox-1 binds to MMP14 promoter and represses its transcription),therefore prevents the repression of MMP-14 by prox-1 and induces mmp-14 expression	[121]
HTLV-1	TAX	MMP-2 MMP-9	Induces the gelatinase activity of MMP-9 and MMP-2 in endothelial cells and downregulates the tissue inhibitor of MMP	[134]
		MMP-9 MMP-3	Increases expression of MMP-9 and MMP-3 bysecreted proinflammatory cytokines (IL-1alpha, IL-6, TNF-alpha) by infected glial cells with HTLV-1	[134, 135]

Moreover, the results of a study by LU et al. provide molecules for the molecular signaling basis of the effects of newly synthesized quinazolinone MJ-29 on the inhibition of metastasis and invasion that could be beneficial as a therapeutic strategy to treat human oral cancer [139].

Accordingly, it can be concluded that 3-azidoWA and MJ-29 as natural MMP-9 inhibitors may have a more effective inhibitory ability on HBV, and HCV-related cancers by attenuating the internal phospho-ERK and phospho-Akt protein expression, which led to the repression of ERK and PI-3K signal pathways.

Other natural compounds such as curcumol via activation of JNK1/2, Akt, and nuclear translocation of NF-κB p65 [140], as well as magnolol through the inhibition of TNF-α by suppressing NF-κB binding activity [141], both caused the reduction of MMP-9 expression in MDA-MB-231 cells, breast cancer cell metastasis, and human urinary bladder cancer 5637 cells, respectively. Meanwhile, there is a possibility that these natural inhibitors can also modulate MMP-9 protein expression through multiple signaling pathways such as JNK, Akt, and TNF-α in HCV-related cancers. Antcin-H, a pure compound that is isolated from A.cinnamomea, can downregulate MMPs through inhibition of the FAK-ERK-C/EBP-/β/c-Fos-MMP-7 pathway, especially MMP-7 expression in renal cancer cell [142] (Table 4).

Table 4: Natural and synthetic inhibitors of MMPs in inhibiting targets of major signaling pathways in various types of cancer

Inhibitor	Class	Selectivity	Type of cancer studied	Inhibiting targets of major signaling pathways	Reference
Batimastat	Peptidomimetic	Broad spectrum	malignant ascites and malignant pleural effusion		[33]
Marimastat	Peptidomimetic	Broad spectrum	Breast cancer, small cell lung cancer, on-small cell lung cancer		[33]
BB-2516	Peptidomimetic	Broad spectrum	Head and neck squamous cell carcinoma (HNSCC)	through interference with autocrine loops in EGFR/c-erbB signaling pathways	[143]
BAY 12-9566	Nonpeptidomimetic inhibitor	MMP-2, MMP -3	advanced ovarian cancer, Breast cancer		[167]
AG3340	Nonpeptidomimetic inhibitor	MMP-2, MMP -3	non-small cell lung cancer		[168]
BMS-275291	Nonpeptidomimetic inhibitor	MMP-2, MMP -9	Non-small-cell lung cancer, prostate cancer, colorectal cancer, Breast cancer		[169, 170]
CGS 27023A	Small molecule	Broad spectrum	Advanced solid cancer		[33]
Col-3 (metastat)	Chemically modified tetracycline	MMP-2, MMP -9	Soft-tissue sarcoma, AIDS-related Kaposi's sarcoma, high-grade gliomas		[171, 172]
Prinomastat	Small molecule	Broad spectrum	Non-small cell lung cancer, , prostate cancer		[136]
Tanomastat	Small molecule	MMP-2, MMP-3, MMP-9	Ovarian cancer, adenocarcinoma of the pancreas, non-small cell lung cancer		[136]
Doxycycline	Tetracycline derivative	Broad spectrum	polycystic ovarian cancer		[136]
SB-3CT	Small molecule	MMP-2, MMP-9	T-cell lymphoma and prostate cancer models		[173]
ND-322	Small molecule	MMP-2/MT1-MMP	melanoma		[174]
curcumol	Major active components in the essential oil of RhizomaCurcumae	MMP-9	Breast cancer cell metastasis	via JNK1/2 and Akt(Ser473)-dependent NFκB signaling pathways	[140]
3 -azidoWA	derivative of Withaferin A	MMP-2	human cervical HeLa and prostate PC-3 cells	concomitant marked reduction in pAkt and pERK signaling by modulating extracellular par-4	[138]
MJ-29	2-phenyl6-pyrrolidinyl-4-quinazolinone derivatives	MMP-2/9	Oral squamous cell carcinoma	Down-regulation of MAPK and AKT Signaling	[139]
antcin-H	pure compound isolated from A. cinnamomea	MMP-7	Renal Cancer Cell	Partly through Inactivation of FAK-ERK-C/EBP-/β/c-Fos-MMP-7 Pathways	[142]
magnolol	the main constituent of Magnoliaceae	MMP-9	human urinary bladder cancer 5637 cells	Inhibition TNF-α-induced MMP-9 expression by suppressing NF-κB binding activities	[141]

The presence of MMP-inhibitory effects in virus-related cancers is still unknown. It has been determined that BB-2516, among all synthetic inhibitors, decreases the protein expression of a broad spectrum of MMPs by interfering with autocrine loops of EGFR/c-erbB signaling pathway in head and neck squamous cell carcinoma (HNSCC) [143]. However, more studies are necessary to understand the connections between MMP inhibitors and these signaling pathways in oncovirus-related cancers, making it especially important to examine how the relationships are.

CONCLUSIONS

In summary, matrix metalloproteinases as cellular proteases play the main role in biological processes as well as pathological conditions, including tissue repair, wound healing, developmental morphogenesis, inflammatory diseases, and tumor progression. Oncoviruses, in many cases, promote tumor progression through multiple mechanisms that affect the expression of these cell proteases. As oncoviruses upregulate the expression of MMPs genes through direct (via DNA binding) as well as indirect interactions (via activating PI-3K/AKT, ERK/MAPK, IFN/JAK/STAT, JNK, NF-κB signaling pathways or immune response), causing escape from the immune system and play a key role in cell proliferation, migration, angiogenesis, EMT, invasion, metastatic features, and subsequent tumor progression. Today, several compounds have been studied as matrix metalloproteinase inhibitors. Various studies have shown that these inhibitors activate the immune system and suppress tumor progression by inhibiting signaling pathways activated by viruses. With these interpretations, these cell proteases may be used as biomarkers to detect different stages of the development of oncovirus-related tumors, soon followed by inhibitors of these proteases in the treatment of viral tumors.

Conflict of interest

The authors report no conflicts of interest.

Abstract: *Background: Cardiovascular disease can be triggered and accelerated by hypertension and the underlying changes in the structure and function of arteries. The purpose of this review is to explore some vascular changes that occur in hypertension as a consequence of the imbalance between cell proliferation and cell death, processes that play an important role in stabilizing the thickness of the arterial wall during vascular remodeling. Methods: The authors conducted research through PubMed and Google Scholar databases using the following search formula: (hypertensive*) AND ((vascular modifications)) OR (vascular changes)) AND (cell death). Results: From 40 articles, only 17 publications were included in this study, taking into account four processes that can be preceded or followed by inflammation and depend on the interaction between local growth factors, vasoactive substances, and hemodynamic stimuli: Cell proliferation and growth; Cell migration; Cell death; Degradation or reorganization of extracellular matrix. Conclusions: To summarize, maladaptive vascular changes in hypertension can represent a major argument for prompt and maximal therapeutic intervention in patients with high cardiovascular risk. Moreover, they can represent an important step in discovering new markers of cardiovascular risk and in the development of new targeted therapies for different pathways of cellular signaling through which the reversibility of abnormal vascular changes could be obtained.*

Keywords: *cell death; inflammation; cellular metabolism alteration; vascular remodeling; hypertension; pathophysiology*

INTRODUCTION

Cardiovascular disease, one of the leading causes of death worldwide, can be triggered and accelerated by hypertension and the underlying changes in the structure and function of arteries. Knowing the pathophysiological mechanisms that are responsible for the maladaptive changes occurring at the vascular level in the context of hypertension, can represent a first step in the development of new targeted therapies for different pathways through which the reversibility of the abnormal vascular changes can be obtained.

Some studies have shown that hypertension linked to the imbalance between cell death and cell proliferation could explain vascular remodeling: accelerates endothelial apoptosis, promotes cell migration, and accelerates the proliferation of vascular smooth muscle cells [1] resulting in the thickening of the middle tunic of the arteries [1,2]. The role of cell death in blood pressure charge is still unknown [3]. The prevalence of hypertension increases with age and the proposed pathophysiological mechanisms are represented by hemodynamic changes, arterial stiffness (due to elastic lamina disruption and intimal hyperplasia), and neurohormonal and renal dysfunction [4]. In the elderly, vascular injuries can heal through the formation of vascular scars due to the increase in the proliferation of smooth muscle cells and the reduction of their apoptosis and decrease in sensitivity to apoptotic stimuli in fibroblasts and myofibroblasts, with secondary fibrosis [5,6].

In terms of the cell death process, some major pathways have been described (apoptosis, necrosis, and autophagy), depending on the injury and the type of cell [7]. Programmed cell death and necrotic cell death sometimes have mechanisms that can be overlapped [5]. The initiation of apoptosis is the result of death signaling pathways, intrinsic (mechanisms triggered by cellular stress through hypoxia, oxidative stress, and ADN damage) or extrinsic (mediated by transmembrane receptors of the TNF receptors family). In apoptosis, an essential process in maintaining tissue homeostasis, as a result of caspase cascade activation and imbalance between pro and antiapoptotic factors, the cell is broken for-ming membrane-bound vesicles and apoptotic bodies (after the shrinkage of the cell, fragmentation of nucleus and chromatin and plasma membrane blebbing [7]) responsible for clearance of dead cells and also for intercellular communication [8]. Necrosis is an accidental form of cell death but in certain instances is initiated or modulated under programmed control mechanisms. Unlike apoptosis, which requires energy consumption, necrosis is a process in which cells die without energy consumption; in the necrotic cell death process, as a result of the breaking of the cell membrane and the elimination of the cell content in the extra-cellular space, inflammation occurs. It has been described as a form of programmed necrosis (necroptosis), caspase-independent, with mitochondrial changes involvement [5]. Another type of cell death, autophagy, is the process through a staving or deprivation of growth factors cell generate energy and metabolites by digesting its organelles or macromolecules. There were also described multiple sub-types of cell death, depending on caspase involvement or the presence of some of the necrosis criteria: aponecrosis, paraptosis, anoikis, cornification, etc [5].

Recent studies examine how certain factors affect endothelial apoptosis in patients with hypertension and other comorbidities [1,4,9]. Endothelial cell apoptosis was found in patients with hypertension and peripheral arterial disease by studying endothelial cell cultures [9]. Vascular cell remodeling, an active process, involves changes in at least 4 cellular processes: cell growth and cell migration, inflammation, cell death, and degradation or reorganization of the extracellular matrix. It is dependent on the interaction between local growth factors, vasoactive substances, and hemodynamic stimuli [10].

Although the in vitro studies [11] demonstrated a relationship between the level of some plasma membrane receptors involved in apoptosis induction (named death receptors) [12] and the phenomenon of apoptosis, the causal link between cell death and vascular changes was not proved yet [11].

Considering that the phenomenon of cell death and cardiovascular outcomes are linked through metabolic risk factors intervention and exogenous causes of cellular stress that lead to cell destruction via different pathways and demonstrating to what extent the alteration of cellular signaling, the alteration of the extracellular environment and the triggering of cell death mechanisms are responsible for the abnormal remodeling of the arterial wall in the hypertensive patients, the research could be directed to discover new markers of cardiovascular risk and new therapies that can be targeted in patients with cardiovascular risk factors. The benefit could be major, the measurement of death receptors levels related to cell death phenomena that can predict cardiovascular outcomes and death [11], in patients with high cardiovascular risk, became a major argument for prompt and maximal therapeutic intervention in this specific populational group.

The purpose of this review is to explore some vascular changes that occur in hypertension as a consequence of an imbalance between cell proliferation and cell death, processes that play an important role in stabilizing the thickness of the arterial wall during vascular remodeling.

MATERIALS AND METHODS

A comprehensive search through PubMed and Google Scholar using the following search formula: (hypertension*) AND ((vascular modifications)) OR (vascular changes)) AND (cell death) was performed. Only full-text freely available articles published in English between 2000 and 2021 were used. Articles that were most relevant to the subject of this review were included after thorough consideration. Inclusion criteria were published in English, publication within the mentioned period, and inclusion of hypertensive models or animal models, or cell cultures studies. From 40 articles, only 17 publications were included in this study. All the selected papers were reviewed by an independent reviewer to check that the interpretations were correct.

Hypertension has a great impact on the cardiovascular system; the thickness of the arterial wall during the remodeling process could be the result of cell death mechanisms triggered by factors potentially involved in the etiology of arterial hypertension. Considering that the connection between cell proliferation and cell death is responsible by a vascular remodeling process in hypertension, we take into account for our study four processes that can be preceded or followed by inflammation and depend on the interaction between local growth factors, vasoactive substances, and hemodynamic stimuli:
- Cell proliferation and growth
- Cell migration
- Cell death
- Degradation or reorganization of extracellular matrix

RESULTS

The search strategy identified 40 articles of which 17 were deemed to be eligible for inclusion in this systematic review. Of these, 12 studies addressed markers of cell proliferation/growth, 7 studies addressed cell migration, 12 studies addressed cell death processes/markers, 7 studies focused on the degradation of extracellular matrix, and 13 studies addressed inflammation markers (shown in Table 1).

In hypertension, the connection between cell proliferation and cell death could be critical in determining the thickness of the arterial wall during the remodeling process. There are 2 types of criteria for classifying cell remodeling:

- according to the size of the middle tunic: hypertrophic, eutrophic, and hypotrophic
- according to the size of the lumen: internal and external remodeling.

The consequences of cell remodeling are:

- high pulse pressure,
- stiffening of the arterial wall
- changes in the extracellular matrix.

All consequences of cell remodeling are determined by the release of growth factors and cytokines. The immune system, namely T lymphocytes, plays a key role in remodeling, more precisely based on a T-reg/T-effector imbalance.

Because of its ability to modify the vascular tone, vascular endothelium plays a significant role in hypertension. Endothelial dysfunction is caused by a reduction in nitric oxide (NO) availability, which causes endothelial dysfunction. The main cause of the decline in NO is the excessive production of reactive oxygen species (ROS)[13].

Blood pressure is affected by the phenomenon of cell death that can occur at different levels of the arterial wall, however, in hypertension the role of different types of vascular cell death is unclear. Researchers discovered that vascular smooth muscle cell growth is increased by cell death [1]. The cell death process is thought to play a key part in remodeling, but it is unclear whether it is the main process or a growth-related compensatory mechanism, being influenced by reactive oxygen species, NO, angiotensin type 2 (AT-II), and endothelins.

Due to vascular damage, elevated blood pressure values may alter the integrity of the endothelium and may also represent a risk factor for the onset and progression of vascular atherosclerosis changes leading to the destabilization of atheroma plaques [14]. Atherosclerosis favors the processes of inflammation and necrosis of the blood vessel and plaque can become unstable without proper treatment and cause even more complications.

DISCUSSION

In our study, we collected a lot of information about vascular modifications in hypertension. From the 17 selected articles, in 15 we found information about vascular remodeling (88.23%), in 14 articles we found arguments for the presence of the inflammatory phenomenon (82.35%), 13 articles (77.47%) argued for the presence of cell death and also 13 described cell proliferation, 7 articles (41.17%) described the phenomenon of cell migration, and 8 articles (47.05%) described reorganization of the extracellular matrix.

Starting from the information provided by the articles included in our study, our hypothesis related to the involvement of cell death at the vascular level in arterial hypertension seems to be valid. Maintaining a balance between the processes of cell proliferation, cell migration, cell death, and degradation of the extracellular matrix could ensure adequate vascular elasticity and delay the installation of specific hypertensive vascular changes. It seems that cells from all layers of the vascular wall are involved and can be affected by different types of death, the damage to each cell type leading to cellular metabolic changes and changes in the extracellular environment.

Vascular tone and vascular remodeling

The endothelial cells which form the tunica interna of the arterial wall, are essential for regulating hemostasis, vascular tone, and host defense [15]. Secretion, protection as a barrier, and local metabolism are the endothelium's three primary activities, each of which is altered by hypertension. The endothelial cells produce vasoactive substances such as nitric oxide (NO), carbon monoxide (CO), hydrogen sulfide (H2S)[15], prostacyclin (PGI2), endothelin 1 (ET-1), AT-II, prostaglandins. Normally, there is an equilibrium between these substances to maintain proper blood flow. In hypertension, at the vascular level is an increased production of vasoconstrictor factors (ET-1, AT-II, prostaglandins) which determine endothelium dysfunction (increased permeability, induce inflammation, and edema). It was discovered that the substances and structures that are released from a cell when it dies can affect the endothelial function in an autocrine, paracrine or endocrine model [16].

The endothelium is important for both short-term vascular tone modulation and long-term vascular remodeling. Nitric oxide is the most significant endothelium-derived vasodilator molecule which, under healthy conditions, is capable of inhibiting the primary fundamental pathways driving the formation of atherosclerosis and thereby improving vascular health. Reduced NO availability and endothelial dysfunction are caused by NO breakdown by reactive oxygen species (ROS) in physiological aging and many pathological diseases, including arterial hypertension.

Essential hypertension patients (HT) had a lower endothelial response to acetylcholine (Ach) than normotensive people (NT) in each age group, but it was proved that the vascular response to Ach in both HT and NT patients decreases as they become older [17]. In the pathogenesis of endothelial dysfunction and the cardiovascular consequences related to endothelial inflammation [18], apart from the effects of nitric oxide and carbon monoxide, the role of hydrogen sulfide has been also described. H2S formation was detected in smooth muscle cells, vascular endothelial cells, and cardiomyocytes and it was shown that H2S could protect endothelial cells against apoptosis by attenuating the overproduction of ROS and inhibiting mitochondrial apoptosis [15].

The vascular smooth muscle cells (VSMCs) that form tunica media are responsible for vasoconstriction, vasodilatation, and the process of remodeling [19]. The hyperplasia and hypertrophy of VSMCs are the processes that underlie vascular remodeling. The most frequent type of remodeling in hypertension is the inward type causing the narrowing of the arterial lumen. The outward type of remodeling occurs during anti-hypertensive treatment and is also caused by increased blood flow[16]. Some studies have revealed that a marked cell death influences and accelerates the proliferation of vascular smooth muscle cells, resulting in the thickening of the middle tunic of the arteries [2]. As a result of cell death through necrosis and the breakdown of plasma membrane integrity, the contents of necrotic cells are released, triggering a proinflammatory response [3].

Fibroblasts that form the tunica externa secrete chemokines, cytokines, and growth factors that contribute to normal vascular function and participate in the degradation of the extracellular matrix components. They play an important role in remodeling as a response to injury. However, fibroblasts suffer structural changes that are accompanied by proliferation and migration into the tunica media during hypertension [16].

Cell remodeling

Cell remodeling involves cell growth and cell migration, cell death, and degradation of the extracellular matrix and is dependent on multiple factors [10]. The media-to-lumen ratio (M/L), modifying the vessel wall width for increasing muscle mass, the reorganization of cellular and noncellular elements and the lumen dimensions are the most prominent manifestations of these adaptations [20]. As a result, remodeling can be classified based on the degree of change of the medium arterial tunic in hypertrophic, which is the most common, hypotrophic, or eutrophic remodeling, as well as the size of the lumen in internal or exterior remodeling [21]. With age, large arteries undergo outward hypertrophic remodeling and stiffening [4], and in hypertension, this process may be accelerated, resulting in higher pulse pressure [22-24]. The elastic laminae, on the other hand, develop multiplication and fragmentation in severe hypertension, with increased deposition of collagen and fetal fibronectin, leading to greater stiffness [23]. Small artery remodeling has typically been associated with increased media thickness in hypertension, but new studies have shown that there are two forms of remodeling, inward eutrophic and inward hypertrophic, depending on whether the media cross-sectional area is enlarged [23]. The discovery that inward eutrophic remodeling may be prominent in some kinds of hypertension has raised the prospect that countervailing mechanisms in hypertension, including apoptosis, may compensate for or modify growth [23,25]. The outer and lumen diameters are decreased, the media cross-sectional area is unchanged and the M/L is increased without stiffening in inward eutrophic remodeling [25]. Inward eutrophic remodeling reduces the outer diameter of the vessel through a mix of growth and apoptosis, with apoptosis concentrated to the periphery, whilst inward growth decreases lumen diameter, which may explain the preservation of media volume. It is uncertain whether apoptosis is a growth-related compensatory mechanism or a primary process[25]. Mechanical forces exerted on the arterial wall also play a significant role in remodeling. Changes in the extracellular matrix, the cellular release of growth factors and cytokines, and vascular sensitivity to circulating humoral factors are all caused by them. Force duration, load, and force properties all have an impact on all of these factors [1].

Low-grade inflammation

In hypertension and cardiovascular disease, low-grade inflammation plays a critical pathogenic function [26-28]. Innate and adaptive immune systems, specifically T cells, are implicated, according to a significant body of research. T-lymphocytes play a key role in the development of hypertension-related vascular remodeling. The balance between T-effector and Treg lymphocytes is a critical regulatory system that, when disrupted, favors blood pressure increase and the development of organ damage [21]. Treg lymphocytes have potent anti-inflammatory characteristics, ensuring vascular homeostasis and protecting the arterial wall against the onset of atherosclerosis [21,29]. In humans, the majority of data establishing essential hypertension as a chronic low-grade inflammatory state found a clear and independent link between c-reactive protein (CRP), tumor necrosis factor (TNF), Interleukin 1 beta (IL-1 beta)[30], Interleukin-6 (IL-6), and adhesion molecules and vascular alterations in essential hypertensive patients [21].

An important role in the process of vascular remodeling is played by the renin-angiotensin-aldosterone system (RAAS)[29,31] because of its role in VSMC migration and inflammation [24,32]. This system acts through 2 types of angiotensin II receptors AT1-R and AT2-R, but the AT1-R is thought to be the primary receptor that causes Ang II's proliferative and profibrotic actions [20,33]. The AT2-Rs are thought to cause opposite effects, preventing vascular deterioration. But there are times when AT2-R acts similarly to AT1-R (for example, in renovascular hypertension it causes tonic renal medullary vasoconstriction) [32,34]. Recent studies showed that there exists an AT1-R autoantibody (AT1-AA) which is an agonist of AT1-R. AT1-AA raises AT2-R expression and encourages cell migration through cytoskeletal remodeling [34]. The RAAS is implicated in physiological and pathological actions when it comes to vascular changes. It reduces ROS generation and modifies vascular tone via vasoconstriction and vasodilatation. During hypertension, this RAA system induces fibroblast proliferation, collagen deposition, and vascular hypertrophy [20].

Cell death

Apoptosis is a type of gene-controlled cell death that was first discovered in development as a mechanism for fine-tuning growth. The vascular system has a large number of apoptosis modulators. Reactive oxygen species, NO, angiotensin type 2 receptors, and the endothelin system are all possible candidates. Reactive oxygen species play a key role in the pathogenesis of hypertension and vascular cell apoptosis [35], with O_2^- inducing proliferation and H_2O_2 inducing apoptosis through a protein kinase C–dependent pathway, respectively. Angiotensin II is also a potential apoptotic trigger [25,31,36].

Recent studies examine how certain factors affect endothelial apoptosis in patients with hypertension and other comorbidities. Endothelial cell apoptosis was found in patients with hypertension and peripheral arterial disease (PAD) by studying endothelial cell cultures. They demonstrated that physical activity can lower this type of cell death[9]. PAD patients present increased cardiovascular stress, inflammation, and oxidative stress. Inflammation and oxidative stress speed up the progression of myopathy and increase the risk of apoptosis and sarcopenia. In older persons, exercise decreases oxidative stress and improves reactivity to oxidative processes [9].

Inflammation, VSMC apoptosis, and oxidative stress in patients with hypertension [1,18,19] can also play an important role in the pathology of abdominal aortic aneurysm AAA [37,38]. According to some studies [39] a member of the seric proteinase inhibitor superfamily, Human Kallistatin, acts as a protective factor by blocking the pathway that stimulates AAA generation [39], and even whey-protein supplementation has a beneficial effect, improving vascular function by inhibiting the serum angiotensin-converting enzyme [40].

Lesions that appear on the arterial wall and the dysfunction of endothelial cells determined by high blood pressure values are factors that contribute to atherosclerosis. In the injured artery intima, extra low-density lipoprotein (LDL) accumulated suffer processes of oxidation and can attract monocytes and macrophages, forming the foam cells. The local inflammatory reaction is severe [41] and it triggers a cascade of events [38,42]. Foam cell secretion, deposition, and apoptosis [43] are crucial steps in the occurrence of atheroma plaque [44]. In advanced stages, the macrophage function of phagocytosis is destabilized, the atheromatous plaque continues to grow and, in the end, it will become unstable, promoting local inflammation and necrosis without the proper treatment [41]. Studies have revealed that at the cellular level microRNA plays a role in the control of atherosclerosis [41,45], acting on the TGF-β signaling pathway, inducing proliferation, migration, and apoptosis of endothelial cells, VSMCs, and macrophages [37,43,46].

Sometimes, associated with long-term uncontrolled hypertension and left ventricular dysfunction (or other conditions such as left heart disease, thromboembolic pulmonary condition, lung disease, liver disease, hematologic disease, metabolic disease, connective tissue disease, human immunodeficiency virus infection, thyroid diseases, etc.), pulmonary hypertension may occur [47,48]. In this situation, through the lungs arteries that have a reduced lumen and thickened walls, blood will flow slowly. Pulmonary arterial hypertension (PAH) is defined by mean pulmonary arterial pressure (mPAP)>20 mmHg at rest assessed by right heart catheterization [47-49]. Histopathological changes at the pulmonary level are neointima formation in pulmonary arteries, wall thickness, and plexiform lesions formed by the proliferation of endothelial cells. There is an increased level of ROS that contributes to oxidative stress and vascular remodeling [50], similar to the changes found in the arteries of hypertensive patients. It has been discovered that there is a deficient activity of NO-synthase, the level of NO is low and so are the vasodilatory effects. The role of proapoptotic and antiapoptotic proteins has been incriminated in the initiation of the pathogenesis of PAH and the proliferation of apoptosis-resistant vascular cells [51,52]. Both reversible and irreversible PAH express the apoptotic markers (caspase-3 and p-53) [51,53], while irreversible PAH expresses BCL-2 only in severely wounded endothelial cells [51]. Apoptosis plays an important role in pulmonary hypertension among the proliferation of VCMCs and plexiform lesions [51,52].

In our study we highlighted some evidence in favor of the hypothesis that cell death is involved and has consequences on vascular changes in people with arterial hypertension; the vascular changes occurring in the hypertensive patient may be due to the alteration of the cellular metabolism, which may represent a triggering factor of cell death processes by activating abnormal cellular signaling pathways. However, there are insufficient data to show the cell death types involved and the types of cells in the vascular walls involved in the process of vascular remodeling, therefore we consider that further studies are necessary to elucidate these aspects

CONCLUSIONS

Cell death and cardiovascular outcomes seem to be linked through metabolic risk factors intervention and exogenous causes of cellular stress. Demonstrating that alteration of cellular signaling, the alteration of the extracellular environment, and abnormal cell death mechanisms are responsible for the abnormal remodeling of the arterial wall in hypertensive patients could direct future research toward the identification of new molecules as plasma membrane receptors involved in apoptosis and new therapies that can be targeted in patients with cardiovascular risk factors. Once the vascular impact of imbalances between cell proliferation and cell death will be demonstrated, its early detection could become an argument for maximum therapeutic intervention in this population group.

Conflicts of interest and sources of funding
The authors declare no conflict of interest.

Authors' contribution
EB conceived of the presented idea. AMD, EB contributed to documentation on the topic of interest, work conception and revised the manuscript. EB, ŞSB, OA performed the final revision of the manuscript. All authors discussed the results and contributed to the final manuscript. ŞSB and OA gave final approval. All authors have read and agreed to the published version of the manuscript. EB, ŞSB, OA had equal contributions.

Abstract: *This article aims to highlight the burnout burden among neurologists and provide information on some of its causes and consequences. We report an original article that reviews our current understanding of burnout matter in the neurology field. The main search engine through which we performed extensive literature research was PubMed, Scopus, and Google Scholar. The following information was collected: triggers of burnout and factors that perpetuate it, major complaints, values, and goals that dictate how coaching with it. Physician burnout is an umbrella term characterized by symptoms determined by exposure to chronic workplace stressors. Simply put, it encompasses many dimensions: emotional exhaustion, feelings of cynism, detachment (depersonalization), and a sense of ineffectiveness at work (low personal accomplishment). Burnout is common among all medical specialties, but neurology ranks at the top of the list. Several identified factors continue to fuel this problem. Properly addressing them, rethinking practice, and implementing wise, modern strategies can make significant contributions to reducing it. Aside from the chronic harm to the physician, burnout puts at risk the healthcare community at many levels including patients, other professionals, finances, etc. This paper wants to emphasize that burnout in neurology should be regarded as a global crisis. Thus, some strategies are proposed.*

Keywords: *neurology, burnout, work-life, emotional exhaustion, stress, fatigue, depersonalization, second-victim phenomenon, complaints, functional neurology*

INTRODUCTION

Physician burnout is an umbrella term characterized by symptoms in response to prolonged exposure to chronic stressors related to the workplace. This topic attracted interest from researchers since it exhibits a concerning prevalence. In the field of medicine, we can consider burnout a pandemic that has a negative impact both on doctors and their patients, but most of the time this reaches far beyond that, to families and the overall healthcare system. All medical specialties are affected, but some of them carry a higher percentage of burnout. Over 40% of general physicians experienced at least one symptom of burnout, neurology being ranked the second specialty affected, with more than 60% of neurologists signaling symptoms [1,2]. Medscape 2022 report on Physician Burnout and Depression showed that 47% of neurology specialists are experiencing mental health challenges, which represents a substantial increase in its prevalence compared with the previous year's reports when it was 42% [3]. The purpose of this article is to highlight the burnout burden among neurologists and provide information on some of its causes and consequences.

BURNOUT AND NEUROLOGY

To date, many research studies have contributed to a comprehensive overview and understanding of the root causes that fuel physician burnout.

The prevalence of neurological disorders increased in the last two centuries and the increased burden that comes along can be attributed to explosive population growth, people reaching older ages, unhealthy lifestyles, and unawareness of the importance of prophylactic measures [4].

In opposition to this growth, the global shortage of neurologists led to inequalities in the availability of patient care with those already existing clinicians being overwhelmed. The Association of American Medical Colleges biannually investigates the number of patients per active physician. Reports published two years ago indicated that the number was higher in neurology (23.429) than in ophthalmology (17.162), cardiovascular diseases (14.717), radiology (11.896), psychiatry (8.544), emergency medicine (7.332), internal medicine (2.758), and is approaching specialties with the highest burnout rates such us urology (32.490) [5]. Thus, the low number of practicing neurologists per patient increases the amount of work, compromises patient care, and exacerbates burnout.

Switching to professional working hours per week, an interesting study concluded that neurologists worked 57.1 hours per week, with 42.3 hours being spent performing inpatient activities. In our neurology department, the average number of professional working hours per week is 59, with a peak of 100 on rare occasions (absenteeism of other colleagues because of medical conditions/vacations or lack of staff) [6].

From a holistic point of view, burnout can be regarded as an indicator of quality and duration of life, given that it has a direct damaging effect on health: overnight shifts, exposure to all kinds of infective agents, irregular and exaggerated effort, lack or inadequate physical exercise, emotional detachment, interrupted meals or maladaptive coping strategies such as excessive caffeine intake or other power drinks, alcohol, and drug abuse. Johann Ludwig Casper, a prominent name in forensic medicine stated that there is no profession with a comparable physical and mental force demand as the medical one, an observation comparable with recent studies [7]. It is also worth mentioning that being on call requires working very fast or accomplishing more tasks being short on time. Very similar ideas are presented in a meta-analysis of 17 studies that in people with high demands, the risk of mortality is 20% higher than in the reference group [8]. Similar opinions are found in a study involving 1.671 American neurologists, where 60.1% of the responders had at least one symptom of burnout [2].

According to the World Health Organisation and International Classification of Diseases, burnout has become 2019 a legitimate medical disorder and has been given its ICD-10 code (Z73.0 - Burn-out state of vital exhaustion). Burnout is a state of chronic stress, that occurs after the body system is repeatedly triggered. It can exacerbate mental conditions like anxiety disorders, depression, and sleep problems. Some authors focused on the cortisol secretion parameters and concluded burnout is a mental syndrome with unique pathophysiology [9]. Moreover, as it often happens, the presence of a disease leads to a higher chance for another one to develop. Burnout influences not only subjective well-being but other biological processes as well. In a large study of nearly 9000 employed adults, was found that burnout is a significant risk factor for developing coronary heart disease and finally, heart attacks [10]. These findings support the idea that physicians with high demands as neurologists are exposed to challenges regarding their health and are more vulnerable to stress and burnout.

There is an excessive workload and clerical duties, including finishing notes, phone calls, ordering tests and reviewing results, responding to phone calls and patient requests, and prescribing medication. Assessing indicators related to burnout in a national survey on 9561 neurology residents and fellows after studying 354 responses to the survey the following was revealed: regarding the amount of time spent on clerical tasks directly related to patient care" only 26.2% of residents and 29.7% of fellows agreed that it is reasonable [2]. Another particular challenge is finding meaning in work and this often translates to helping others. Some neurological disorders do not come with treatments or cures or are associated with a significant burden of disability. In the same study, in the matter of, satisfaction with the job" only 68.9% of residents and 63.1% of fellows were more likely to be satisfied with their career choice and in line with, work being meaningful", 78.8 % of residents and 85.6% of fellows had positive feelings towards their job [11]. In comparison to attending physicians, an important number of neurology residents experience burnout due to extra workload and the challenges that come with a new environment, 73% of residents mentioned at least one symptom from the constellation of burnout. Furthermore, both residents and practicing physicians are affected by the second-victim phenomenon, which refers to feelings of guilt caused by medical errors which result in poor patient outcomes [12,13].

Some authors focused instead on sources and outcomes of burnout, on potential interventions to treat it or to prevent the onset. It must be mentioned that burnout is a consequence of systemic deficiencies rather than a result of poor uncoping skills. Increasing trainee resilience and cutting clerical tasks through hiring administrative workers or through using user-friendly technology [14], positive reinforcement and support during residency, and implementing regular burnout evaluations such as Maslach Burnout Inventory. The last one mentioned is the most widely accepted evaluation of burnout and outlines three key aspects of this response: the state of feeling emotionally worn out, feelings of cynicism toward work, and a personal sense of inefficiency in the workplace [15].

The supply-and-demand issue that perpetuates burnout and challenges patient care in neurology could be overcome by recruiting other medical staff. For example, nurse practitioners could get in charge of some medical tasks, without actually exceeding their abilities, as the healthcare oath foremost promotes abstaining from all intentional wrong-doing and harm. This topic with potential usefulness has already been addressed in an article published in the JAMA journal, but it aroused a lot of controversies [16]. Most complaints came from those in need of help, like physicians, stating that to figure out the pathology, prove competency, and be able to give medical assistance one has to go for over a decade in training. This amount of time is spent in school only by doctors, to fully become licensed, and no other alternative shorter programs can replace this training. But maybe they can approach it. An answer to this problem could be by enhancing nonphysician practitioners in medical student courses or by attending residents, giving them templates and free access to educational programs. In conjunction with this, in the UK for example, specialist nurses are known for their crucial role. They can choose and qualify for various neurological conditions (multiple sclerosis, Parkinson's disease, and epilepsy). Sometimes they can order tests, administer basic treatments, and in some states even prescribe medications.

Another indicator of burnout and shortage of neurologists is also projected by the difficulty in making an appointment for new patients and by lengthy waiting lists. Data from 626.000 first appointments scheduled in 2016 with 1.044 providers concluded that wait times for new patients are longer for high-demand specialties, with neurology patients waiting approximately 32.3 days for first appointments [17]. This is particularly relevant since waiting for more than a month often determines patients to cancel their appointments, and never return to the clinic with consequences resulting from delayed diagnosis and treatment. Moreover, significant information was revealed by 2021 research on NHS data conducted by Neurological Alliance – a coalition with over 80 organizations including the MS Society, Parkinson’s UK, and MND Association. Thus, they showed that by the end of March 2021, over 150.000 people were waiting for an assessment by a specialist and over 10.000 of these have been waiting for over a year [18]. These numbers indicate how overwhelmed are the neurology services, putting a lot of pressure on existing physicians, and prolonging a state of excessive stress and fatigue that is burnout.

As a consequence of different workplace stressors and poor coping mechanisms, it was estimated that 10-15% of doctors will develop a problem with substance addiction at some point in their careers [19]. Regarding the neurology field, in a published survey among all specialties, answers from 470 chronic pain/neurology subjects as well, it was shown that in this category of physicians there is a prevalence of 3.7% marijuana use. The issue is not limited to illegal drugs, pain medicine, and alcohol count as well. The anonymous questionnaire indicated a prevalence of 88.6% of alcohol use in physicians from the category of chronic pain/neurology, also being the group with the highest prevalence for benzodiazepine of 15.5%. In addition to this, they found 16.3% prevalence for minor opiates and 1.9% for major opiates, hence being ranked the third specialty. Neurologists frequently come across chronic pain patients in need of benzodiazepines and opiates and somehow this exposes them to these drugs. They ranked second only to psychiatrists in the matter of the risk of using benzodiazepines [20].

Many neurologic diseases require interdisciplinary care and this sometimes creates the setting for conflict between providers offering healthcare services [21]. To reduce the burnout burden, neurologists should try to understand and develop the concept of teamwork. Literature describing the issue of individual vs. teamwork in neurology is scarce, but limited evidence suggests there are more benefits from the adoption of a teamwork approach, where feasible. By avoiding professional isolation, rethinking professional roles, and abandoning territorial behavior.

Receiving complaints is another issue that lies at the heart of burnout in neurology as well. Many of these complaints arise from the limits that go along with disabling or cureless illnesses, giving a false feeling that the healthcare workers did not do anything possible to resolve the case. This situation can be overcome by improving the informative part of the medical act with better communication skills with the patient and through offering honest expectations for patients and their families. Moreover, it is not uncommon that patients to have a low level of medical education and not understand the limits of medicine, priorities, or medical procedures, so this is another important factor that promotes complaints [22,23].

We propose some strategies for the prevention of burnout on neurology specialists (Table 1). There are three categories of factors: related to patient education, related to the workplace, and the healthcare system, and factors related to patient education. An important contributor that fuels burnout is the offering of patients by medical professionals who come across neurological diseases in their practice and whose residency programs do not provide minimum knowledge. Many of these patients have functional neurological disorders which do not always require neurologist interventions. The same problem is with incidental findings on brain imaging such as minimal white matter changes with the improbability of multiple sclerosis or other significant CNS diseases. Poor medical knowledge, not understanding the limits of medicine, medical priorities, or investigations are factors of complaints between relatives. Time-consuming work, the complexity of neurological diseases, communicating a difficult diagnosis, or spending more time doing bureaucratic tasks than caring for patients, all of these are frustrating. Adequate working conditions, generous salaries, creation of functional interdisciplinary teams, filling vacancies, and introduction of telemedicine and artificial intelligence in the field of neurology, would be some solutions for attracting young doctors to this specialty.

Table 1: Significant factors contributing to burnout among neurologists and strategies for prevention

Main factors related to burnout	Proposed solutions
Factors related to the patient education	
Many referrals to neurology that do not need neurology intervention Eg: Functional neurology (often, patients with functional conditions tend to show more dissatisfaction) [22].	Educational initiatives/ online courses targeting other medical professionals that send patients and have minimal to no knowledge of common neurological diseases. Early neuroscience curricula in medical school.
The pandemic of cardiovascular risk factors: high blood pressure and cholesterol, obesity, smoking, and poor diet - put a person at high risk for neurological diseases as well.	Preventive medicine. Screening programs and campaigns to raise awareness.
Factors related to the workplace and healthcare system	
Complaints from patients/families arise from: - the poor medical knowledge - not understand the limits of medicine, medical priorities, or investigations (23)	Legal assistance for the doctors involved.
Shortage of neurologists because of not choosing the specialty [24].	Programs in medical school promote and value neurology. Adequate salary.
Neurologists choose urban over rural settings [25].	Improving rural health settings. Providing medical tools/gadgets/making technology available so the rural residents have equal opportunities to receive medical treatment.
The complexity of neurological diseases creates a job mismatch.	Development of team-based neurologic care Increased need for subspecialty medical care Eg: In Romania, there are no specialists in movement disorders or neuro-ophthalmology
Responsibility fatigue at the workplace.	The schedule of work must be dependent on the complexity of the tasks.
The neutral attitude of the hospital management board [26].	Providing support, understanding human needs, expand vacation policies.
Many rescheduling of appointments decreases physician and healthcare system efficiency overall.	Telemedicine and e-consults increase the capacity to respond to the demand for care and help patients with difficulties in coming to their clinic visits [27].
Mounds of paperwork - spending more time doing bureaucratic tasks than caring for patients. Lack of access to medical records - especially in older patients with many investigations.	Digitalization and artificial intelligence are the future of healthcare. Enabling tracking system for ordered tests/ follow-ups.
Time-consuming tasks. Eg: documenting a history of falls in Parkinson	Artificial intelligence Eg: smartwatches or other wearables that quantify falls or periods of inactivity and already provide a pattern or a conclusion.
Factors related to the physician	
Communicating a difficult diagnosis (often the first interaction occurs already at the time of critical illness).	Programs/Training courses that will help doctors improve their medical communication with patients.
The emotional burden of the specialty itself.	Providing necessary psychological assistance to guide neurologists facing mental health problems like depression or anxiety.

CONCLUSIONS

Overall, burnout can be regarded as a matter of specialty, and it has built up slowly over time, creating a vicious cycle, perpetuated by workforce dropout or choosing other medical specialties with a better lifestyle. Identification of burnout effects in neurology is policy relevant for some reasons: it affects the overall healthcare system with all its components, work-life integration (family), emotional and physical well-being, and social engagement. To conclude, it must be regarded as a worldwide issue.

Abstract: *Background: Infection and sepsis represent major complications after abdominal surgery for secondary peritonitis. Finding new tools that can help identify patients at risk for developing postoperative complications is of the utmost importance for clinicians. We tried to evaluate the use of different biomarkers in evaluating the postoperative prognosis of patients with secondary peritonitis. Methods: We searched the available literature on the usefulness of serum biomarkers in evaluating prognosis in patients with secondary peritonitis. Results: Elevated postoperative lactate levels and high procalcitonin (PCT) levels were associated with negative outcomes. C-reactive protein values increase rapidly in response to the surgical insult but have no value in assessing the overall prognosis. Conclusion: Procalcitonin (PCT) is superior to other biomarkers in predicting severe septic complications and overall mortality in patients with secondary peritonitis.*

Keywords: *biomarkers, peritonitis, C-reactive protein, lactate, procalcitonin, presepsin*

INTRODUCTION

Secondary peritonitis is a condition caused by the spread of bacteria and contents of intraabdominal organs into the peritoneal cavity [1] and is the second leading cause of sepsis in intensive care units worldwide [2]. Overall mortality is 6%, but mortality rises to 35% in patients who develop severe sepsis [2]. Secondary peritonitis requires immediate surgical intervention but after the initial procedure, persisting or new-onset abdominal sepsis continues to be a major problem in the postoperative course [3].

Using clinical symptoms such as fever, tachycardia, tachypnea, non-specific laboratory findings, and scoring systems are valuable tools to assess overall severity and prognosis but will not allow a differentiation between an infectious and non-infectious etiology of a systemic inflammatory response. The clinical assessment of sepsis biomarkers has gained considerable interest in identifying patients at risk for severe complications following surgical intervention for secondary peritonitis [1].

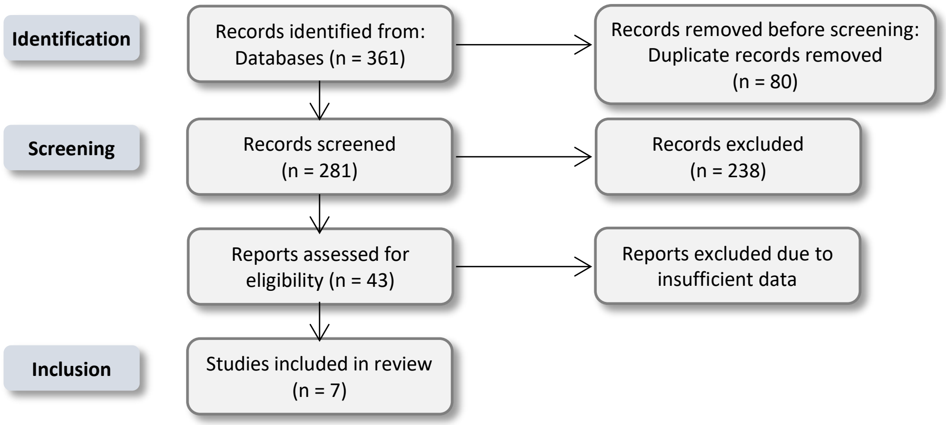
This review aimed to identify the most important biomarkers evaluated in patients with secondary peritonitis and their association with prognosis.

MATERIALS AND METHODS

We searched in three databases using the keywords „peritonitis“ and „prognosis“ in the title or abstract AND specific biomarkers by full name and abbreviated form in full text: lactate, C-reactive protein (CRP), procalcitonin (PCT), presepsin.

Due to the scarcity of the results, a broader search was conducted using the keywords „peritonitis“ AND „biomarker“ to ensure that all relevant literature is covered. The search was last updated on 24/06/2022. A total of 361 publications were primarily retrieved in PubMed, Embase, and Web of Science. No articles were added after manually searching major scientific journals and other references. After excluding 80 duplicates, 281 titles were screened for eligibility and 43 articles were assessed for full-text evaluation. Only English-written human studies were accepted and most articles were excluded due to irrelevancy. We focused only on circulating biomarkers for prognosis in secondary peritonitis. No cut-off point was set for the date of publishing due to the paucity of articles. At the end of the process, seven articles were included in the review. The search strategy is detailed in Figure 1.

Figure 1: Search strategy – identification of studies via databases and registers



Identification
Records identified from: Databases (n = 361)
Records removed before screening: Duplicate records removed (n = 80)
Screening
Records screened (n = 281)
Records excluded (n = 238)
Reports assessed for eligibility (n = 43)
Reports excluded due to insufficient data
Inclusion
Studies included in review (n = 7)

OVERVIEW OF THE SELECTED ARTICLES

Seven articles were included in the current review. Four studies were prospective and three were retrospective, and one study included a control group. Biomarkers of interest were lactate, procalcitonin, and C-reactive protein. No study evaluating presepsin was identified. All studies focused on mortality and severity of septic shock induced by secondary peritonitis.

Further details on the selected studies are summarized in Table 1.

SERUM BIOMARKERS CORRELATED WITH PROGNOSIS IN SECONDARY PERITONITIS

Lactate

Lactate is the metabolic end product of anaerobic glycolysis. Approximately 1500 mmol of lactate is produced daily in all tissues, but mostly in skeletal muscle, brain, intestine, and red blood cells [6,9]. The concentration of arterial lactate is a reflection of the delicate balance between net production and clearance. Disturbances in lactate production, clearance, or both lead to hyperlactatemia and it is seen in a variety of conditions such as sepsis, shock, cardiac arrest, tissue hypoxia, burns, or after some pharmacological agents [6].

The prognostic value of lactate in patients with secondary peritonitis was evaluated in four studies. Negi et al. conducted a prospective study to evaluate the utility of arterial lactate measured on admission (AL1) and 24h after surgery (AL24) as well as lactate clearance as prognostic indicators for mortality in patients with secondary peritonitis. The study concluded that mean values of initial lactate, postoperative lactate, and percentage lactate clearance correlated significantly with higher morbidity and mortality [6]. Of these three lactate indices, postoperative lactate (AL24) was the most accurate in predicting morbidity and mortality [6]. Elevated lactate levels persisting postoperatively probably indicate irreversible pathophysiological changes and global tissue hypoperfusion, indicative of poor lactate clearance and higher morbidity and mortality. Andreevich et al., after conducting a retrospective study, concluded that increased lactate levels both before and 72h post-operatively were associated with a negative prognostic[8]. In the study conducted by Suarez-de-la-Rica et al., 24h postoperative lactate concentrations predicted mortality in the Surgical Critical Care Units, but overall mortality was predicted better by concurrent high procalcitonin and lactate peak concentrations [7].

Jung et al. conducted a retrospective study that aimed to compare the performance of the qSOFA score alone with a combined score derived from qSOFA and serum lactate levels for predicting in-hospital mortality for patients with secondary peritonitis. The study results showed that the qSOFA score alone has poor sensitivity and a modest predictive performance in patients with secondary peritonitis [5]. The addition of one point for hyperlactatemia (plasma lactate level > 2.0 mmol/L) resulted in improved sensitivity (5). The use of the qSOFA + lactate score can be useful to assist clinicians in immediately assessing the risk of mortality in patients with secondary peritonitis [5].

Most studies agreed that elevated post-operative lactate levels correlate better with negative outcomes than preoperative lactate levels.

Procalcitonin

Procalcitonin (PCT) is the 116-amino acid pro-peptide of the biologically active hormone calcitonin [10]. The clinical value of PCT assessment in infection and sepsis has been investigated in almost every medical discipline so far. Most studies have shown that, in general, only in the presence of systemic host response to bacterial or fungal stimuli, does PCT concentration rise above the reference range of 0.5 ng/mL. However, new data demonstrated an early production of PCT related to tissue damage after trauma and the magnitude of the hypovolemic challenge, yet unrelated to infection (4, 10). We analyzed four studies on the usefulness of PCT measurements in predicting negative outcomes in patients with secondary peritonitis. In 246 patients with intraoperatively proven secondary peritonitis of various origins, Reith et al. showed that PCT is a sensitive parameter for the prediction of severe septic complications. Moreover, the study demonstrated that PCT reflects the effectiveness of the surgical procedure in eliminating the septic intra-abdominal focus in the postoperative course (4, 10). PCT was of excellent prognostic value and achieved a sensitivity of 84% and a specificity of 91% in discriminating survivors from non-survivors within the first four postoperative days [4]. Similar observations have been reported in a study conducted by Rau et al. on 82 patients with intraoperatively proven secondary peritonitis. Pro-calcitonin values were elevated in patients who developed septic multiple organ dysfunction syndromes (MODS) with peak levels on the third and fourth days after the onset of symptoms. Comparing the preoperative and postoperative courses, PCT concentrations were significantly elevated in patients with septic MODS during the immediate postoperative course. A persistent procalcitonin elevation beyond the first week after the onset of symptoms was evident in non-survivors, whereas normal concentrations were measured in survivors [3].

Table 1: Studies focused on mortality and severity of septic shock induced by secondary peritonitis

Author	Study design	Biomarker	No. of patients	Correlation with prognosis
Akcay et al (2014)	prospective	procalcitonin (PCT), C-reactive protein (CRP)	84	Serum PCT levels follow a falling trend after surgery as long as the postoperative course remains uneventful. PCT was a better marker than CRP in following postoperative complications and overall prognosis.
Reith et al (2000)	prospective	procalcitonin (PCT), C-reactive protein (CRP)	246	A reduction in the PCT concentration correlated with improvement in the infection and sepsis and was found in all surviving patients. Compared with the values for CRP, PCT showed significant differences between survivors and patients who died, while CRP did not [4].
Rau et al (2007)	prospective	procalcitonin (PCT), C-reactive protein (CRP)	82	The cumulative analysis of all PCT and CRP values measured in the first, second, and third to fourth weeks identified persisting PCT levels greater than 1 ng/mL as an excellent means to assess the overall outcome. Irrespective of the interval, PCT was significantly better than CRP in assessing overall prognosis [3].
Jung et al (2018)	retrospective	lactate	457	The qSOFA score alone has poor sensitivity and a modest predictive performance in patients with secondary peritonitis. The addition of one point for hyperlactatemia (plasma lactate level > 2.0 mmol/L) resulted in improved sensitivity. The use of the qSOFA + lactate score will assist clinicians in immediately assessing the risk of mortality in patients with secondary peritonitis [5].
Negi et al (2020)	prospective	lactate	224	Mean values of initial lactate, postoperative lactate, and percentage lactate clearance were found to correlate significantly with higher morbidity and mortality in patients with secondary peritonitis. Of these three lactate indices, postoperative lactate was the most accurate in predicting morbidity and mortality [6].
Suarez-de-la-Rica et al (2014)	retrospective	lactate, C-reactive protein (CRP), procalcitonin (PCT)	221	Both PCT and lactate provided early prognostic information, more accurate than clinical scores, for overall mortality [7].
Andreevich et al (2021)	retrospective	lactate, C-reactive protein (CRP)	136	Increased lactate and CRP values both before and 72 h after surgery were associated with negative prognostic. PCT value before surgery was insignificant and only an increase in PCT 72h after surgery was associated with a negative outcome [8].

In a prospective study conducted on 84 patients, Akcay et al. were able to demonstrate that serum PCT levels follow a falling trend after surgery as long as the postoperative course remains uneventful. In addition, they showed that after the surgical intervention PCT was a better marker than CRP in following postoperative complications and overall prognosis in patients with secondary peritonitis [1].

Suarez-de-la-Rica et al. compared the prognostic value of lactate, procalcitonin, and c-reactive protein. Peak lactate (>1,8 mmol/L) and PCT (>100 ng/mL) concentrations were associated with mortality, but peak PCT level was the best biomarker for overall mortality. In this study, concomitant high peak lactate and peak PCT concentrations considered as a single dummy variable were highly predictive of overall mortality [7].

C-Reactive Protein

C-reactive protein (CRP), named for its capacity to precipitate the somatic C-polysaccharide of Streptococcus pneumoniae, was the first acute-phase protein to be described [11]. CRP is an evolutionarily conserved protein. From arthropods to humans, CRP has been found in every organism where its presence has been sought [12].

C-reactive protein is a useful marker of systemic inflammation without discriminating infection from other inflammatory processes [7]. When it comes to the value of CRP in evaluating prognosis in patients with secondary peritonitis, after searching the available literature, we found five studies that included this biomarker. All studies agreed that measured CRP values, which increase rapidly in response to the surgical insult, had no value in assessing overall prognosis. C-reactive protein did not reveal any differences between patients with or without septic MODS or in non-survivors and survivors in the perioperative course [3].

CONCLUSIONS

Although a multitude of biomarkers is elevated in patients with secondary peritonitis in the perioperative course, only a few are reliable parameters for assessing the course and prognosis in this category of patients. Many studies have clearly shown that procalcitonin (PCT) is superior to other biomarkers in predicting severe septic complications and overall mortality. In combination with careful clinical patient assessment, PCT offers distinct advantages for the evaluation of response to treatment and prediction of outcome in patients with secondary peritonitis. In regards to the fact that procalcitonin is a well-known „sepsis" parameter, this may not embrace the real properties of PCT, which remain to be defined.

Further studies must be conducted to obtain more knowledge about the importance of serum biomarkers in patients with secondary peritonitis and their correlation with prognosis.

Abstract: *Introduction: As general population tends to have increasing life expectancy, the risk associated with developing chronic kidney disease (CKD) with multiple incapacitating concequences, also increases. Method: For the present study, we registered the data from the observation files of 37 patients diagnosed with CKD undergoing treatment by chronic hemodialysis and noted the CKD associated diagnoses included in the notion of comorbidities. We monitored their statistical incidence both in the whole group and separately, in women and men using TTEST and CORREL. Results: The median age of the subjects was 55.86 (± 12.00) years. The study population mean weight was 74.90 (± 14.44) kg, with a mean weight of 69.33 kg for female subjects, and 77.92 kg for males, respectively. Diabetes was identified in 35.13% of patients, whilst heart failure was present in 16.21% of patients. Conclusions: Following the analysis of the information about the patients with CKD in the dialysis program, which we included in the study group, we observed the existence of variations that occur with age, significant correlations between age and weight and between albuminemia and weight. The most common comorbidity is high blood pressure followed by anemia.*

Keywords: *chronic kidney disease; chronic hemodialysis patients; comorbidities; plasma albumin*

INTRODUCTION

Chronic kidney disease (CKD) can develop due to a multitude of pathologies that all have in common the evolution to kidney failure, with gradual or rapid loss of the main function of the kidneys, that is to remove waste products and excess fluid from the body [1]. The last stage of the development of CKD, especially in patients who are treated by peritoneal dialysis or hemodialysis, is characterized by multiple organs and systems damage [2].

Not only CKD, but also the treatment of its various manifestations, mainly affect the body tissues and systems, at all levels: nervous, cardiovascular, respiratory, endocrine, hematopoietic, digestive, renourinary [2].

The tendency to increase life expectancy of the population is also associated with an increase of the incidence and prevalence of CKD, considering the already known relationship between aging and decreased kidney function, which is seen as a consequence of the physiological aging of the kidneys [2,3]. An even steeper increase in the number of patients with CKD is expected in the coming years. In this context, the medical goal becomes to slow down the progression to terminal stages, achievable primarily by diagnosing the condition as early as possible [1].

Compared to conservative treatment, extrarenal treatment methods provided clear advantages for patients with chronic end-stage renal disease, the duration and quality of life being considerably superior. There are several methods of extrarenal purrification: peritoneal dialysis, hemodialysis, hemodiafiltration. The decision for each type of treatment is based primarily on medical considerations, depending on the underlying disease and the comorbidities present [4]. Diabetic patients are usually at higher risk of developing more severe forms of chronic diseases (e.g. cancer) [5,6,7]. Peritoneal dialysis is preferred for diabetic patients with CKD as this method of treatment ensures the maintenance of a residual diuresis for a longer time, the prevention of complications due to the present vascular damage, the possibility of intraperitoneal administration of insulin and a better hemodynamic stability than chronic hemodialysis. In cases where the patient has a poor state of hygiene or if peritoneal dialysis does not allow a satisfactory volume control to be maintained, chronic hemodialysis is preferred [4].

MATERIALS AND METHODS

For the study we performed, we registered the data from the observation files of 37 patients diagnosed with CKD undergoing treatment by chronic hemodialysis, in the Nephrology Department of the Bucharest University Emergency Hospital.

We noted their general data and the presence of associated comorbidities, as well as the determined values of plasma albumin concentration.

The statistical data processing regarding the incidence of comorbidities revealed important information for understanding the clinical and biochemical context of this particular type of patient in the hemodialysis department.

Among the tests performed on the patients that had presented for chronic dialysis, we noted the value of plasma albumin concentration, because it is a parameter that provides information about the loss of protein in the urine and the nutritional status of renal patients. We determined the statistical differences between the values from women and men, as well as the correlations between this parameter and age, respectively weight.

We performed the statistical processing using the Student test (t-test) to determine the statistical significance of the differences in the values of the parameters determined in women and men and the Correl test to determine whether there are correlations with statistical significance between the parameters we tracked.

We noted the diagnoses associated with CKD, included in the notion of comorbidities and we monitored their statistical incidence both in the whole group and separately, in women and men.

RESULTS

In terms of gender distribution, of the 37 patients, 13 (35.13%) were women and 24 (64.86%) were men.

The median age of the subjects was 55.86 (± 12.00) years. For the women, the median age was 56.46 (± 10.86) years, whereas for the men it 55.54 (± 12.78) years. Although there is a slight gender difference regarding age, this failed to be statistically significant (p> 0.05).

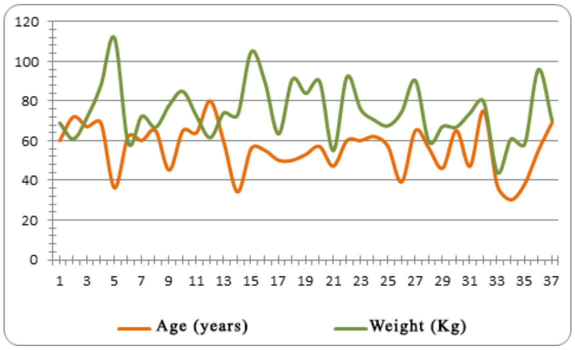
Regarding weight, as presented in Table 1, the study population mean weight was 74.90 (± 14.44) kg, with a mean weight of 69.33 kg for female subjects, and 77.92 kg for males, respectively. As presented in Table 1, this difference was found to be statistically significant, p = 0.01.

Table 1: Average weight and the statistical difference between men and women

	Average weight in women (kg)	Average weight in men (kg)
Average value	56.46	52.27
Standard Deviation	10.87	17.16
p (t-test) 0.43		

Applying the Correl test, we observed that age and weight are two parameters that correlate statistically significantly (p = 0.04) (Figure 1).

Figure 1: Significant correlation between the values of weight and age



For the 37 patients, we noted the value of the plasma albumin concentration and determined the difference in values according to the gender of the patients and the statistical significance of this difference, using the Student test (t-test) (Table 2).

It is observed that the albuminemia values that were determined in these patients are not outside the normal laboratory limits of 3.5-5.2 g/dl (Table 2). By applying the

Correl test, we calculated the statistical significance of the correlations of albuminemia with age and weight (Table 3).

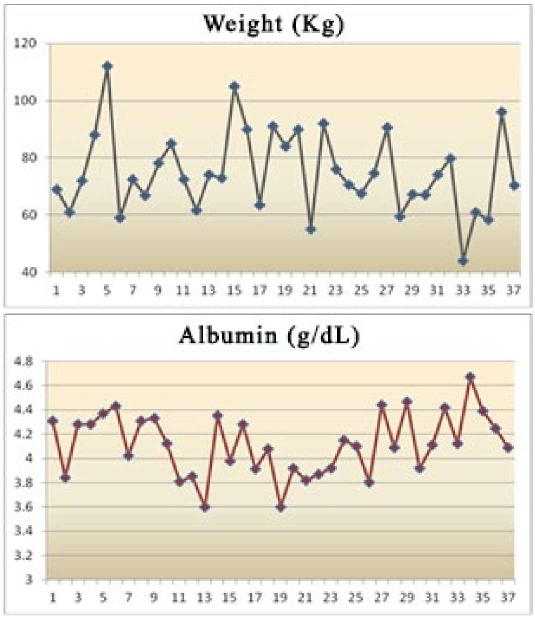
Table 2: Statistical significance of differences in plasma albumin concentrations in patients in the group by sex

Albuminemia(g/dl)		
	Women	Men
Average value	4.10	4.25
Standard deviation	0.24	0.27
t-test	p = 0.41	

Table 3: Statistical significance of correlations between plasma albumin concentrations with age and weight in patients in the group and by sex

Significance of the correlation between plasma albumin concentration and		
	Age	Weight
Women	p = 0.1	p = -0.2
Men	p = -0.37	p = 0.1
Total	p = -0.24	p = 0.02

Figure 2: Correlation weight-albuminemia



We observed that separately, in women and men, the plasma concentrations of albumin do not correlate significantly with age or weight, but, after using the Correl test for the whole study group, a significant correlation between albuminemia and weight has been identified.

We made this determination, knowing that the albumin dosage is a test to assess the general state of nutrition, especially in elderly patients with various conditions, in this category falling most of the patients with CKD in the lot we studied.

COMORBIDITIES DIAGNOSED IN THE STUDIED GROUP

Diabetes mellitus, dyslipidemia, atherosclerosis, hypertension, arteriopathy obliterans of the lower limbs

Diabetes is present in 35.13% of patients, 3 of women and 10 of men, which means 23.07% and 41.66%, respectively. Dyslipidemia occurs in a number of 3 male patients, which means a percentage of 8.1% of the total group. Atherosclerosis is noted in a female patient with kidney disease and in 9 male patients, the incidence rate being 27.02% in the whole group. High blood pressure is a more common comorbidity in patients in the study group: 11 out of 13 women are hypertensive and 23 out of 24 men with CKD are hypertensive. Lower limb arteriopathy is present in only 2 of the male patients, which means 5.4% of the group. Both patients also have diabetes and high blood pressure.

Heart failure, cardiomyopathy, arrithmia, valvulopathy, chronic coronary heart disease

Heart failure is present in 5 of the women and only 1 of the men, this comorbidity is therefore found in 16.21% of patients. Cardiomyopathy is rarer, 1 female patient and 2 of the men in the group, ie 8.1% also have this diagnosis. Arrhythmias are more common in women, 5 out of 14, ie 35.7%, presenting this manifestation in the form of atrial fibrillation with medium or large ventricular allure or in the form of supraventricular tachycardia. Among men, only 2.33% have atrial fibrillation with a medium ventricular allure. Thus, 18.91% of the total group have a form of arrhythmia. Valvular damage is identified in 4 patients out of a total of 37, ie 10.81%, more frequently in women 3 out of 14 and only in 1 male patient. Coronary ischemic disease is diagnosed in 3 women and 6 men, the incidence being 24.32%.

Diabetic/hypertensive/mixed nephropathy, chronic tubule-interstitial nephropathy, autosomal dominant polycystic kidney disease, single kidney, chronic pyelonephritis, chronic glomerulonephritis

Chronic tubulointerstitial nephropathy is diagnosed in a single male patient. The incidence at group level is 2.7%. Out of 13 women in the group, hypertensive nephropathy is present in 2 and diabetic nephropathy in 3 of them, a total of 38.46% with nephropathy. Of the 24 men in the group, 6 have diabetic nephropathy, 4 have hypertensive nephropathy and 2 have mixed nephropathy, a total of 50% of patients with nephropathy. A number of 4 of the 13 women, 30.76%, are also diagnosed with autosomal dominant polycystic kidney disease. Of the 24 men, 4 also have this diagnosis, representing

16.66%. At the level of the whole group, the percentage is 21.62%. Only one male patient has a single kidney, the cause being congenital. The incidence at group level is 2.7%. And pyelonephritis rarely occurs, only one patient, a woman, has this diagnosis. The incidence at group level is 2.7%. More common is chronic glomerulonephritis, which is present in 6 of the men, respectively 25%, and in 2 of the women, respectively 15.38%, with an incidence in the whole group of 21.62%.

Kidney stones, parathyroidectomy, secondary hyperparathyroidism, anemia, chronic viral hepatitis

Kidney stones are present in 2 women and 3 men in the group, which means an incidence of 13.51%. Secondary hyperparathyroidism is diagnosed in only 2 patients, a man and a woman, the incidence is 5.4% in the whole group. Surgical removal of the parathyroid glands was performed in 3 women and 1 man in the group, the frequency being 10.81%. Anemia is more common, 7 of the 13 women, ie 53.8% and 15 of the 24 men, ie 62.5%, have pathologically low hemoglobin. Out of the whole lot 59.45% of patients have anemia. Chronic hepatitis B infection is uncommon as viral hepatitis B is present in 2 women, 1 man in the group is infected with hepatitis B virus and 1 is coinfected with hepatitis B + C viruses. The frequency of chronic viral hepatitis in the group is 10.81%.

DISCUSSIONS

Gender and age are factors that influence some characteristics related to CKD in patients with type 1 or type 2 diabetes, and certain particular aspects of pathogenesis, diagnosis and treatment management have been identified, but the mechanisms are incompletely known and more studies are needed to clarify these connections which would be very useful in order to reduce the number of cases of renal patients and to prevent or control the complications of this condition. Considering the data published by Eriksen O. et al. [5], old age and the male gender are predictors of worsening kidney disease and the rapid progression to severe kidney failure. In the study of Giandalia A et al. [8] the authors concluded that men are more affected, because in their studies, the number of men enrolled is higher than the number of women, results similar to our study where the percentage of men was 64.86%.

Weight is an important parameter in assessing the nutritional status of the patient with CKD. In obese people with CKD, the progression of the disease to renal failure is faster compared to cases of normal weight. Also kidney transplantation or hemodialysis, which may become necessary in advanced stages of the disease, may be more difficult and may have more frequent complications in obese people [9]. After initiating treatment with hemodialysis or peritoneal dialysis, in patients with a glomerular filtration rate below 35 ml/min/1.73 m^2, in stage 3 CKD, weight loss is a factor that increases the risk of mortality by 54% compared to with patients whose weight remains constant. Even in patients with moderate renal impairment, weight loss should be closely monitored and the patient's nutritional status monitored before dialysis is required [10].

In the final stages of the kidney disease, hypoalbuminemia is common, caused by factors that act simultaneously: reduced liver synthesis, increased degradation and renal loss and the glomerular filter membrane is damaged and becomes more permeable allowing the passage of negative albumin molecules from plasma. In our study we observed that separately, in women and men, the plasma concentrations of albumin do not correlate significantly with age or weight. However, applying the Correl test to the whole group, resulted in a significant correlation between albuminemia and weight. We made this determination, knowing that the albumin dosage is a test to assess the general state of nutrition, especially in elderly patients with various conditions, in this category falling most of the patients with CKD in the lot we studied. According to Haller C. et al. [11] the inflammatory phenomenon in kidney disease is also involved in the pathogenesis of hypoalbuminemia. Inflammation correlates with the risk of mortality, hypoalbuminemia is not in itself a pathogenic factor of renal impairment, but is a major predictor of unfavorable prognosis.

Diabetes mellitus is one of the main negative prognostic factors for chronic diseases [12]. According to Anders HJ. et al. [13] the prevalence of type 2 diabetes and CKD increases the incidence of diabetic kidney disease, also known as diabetic nephropathy. The combination of the two diseases can be in the form of diabetic kidney disease if the kidney damage is the consequence of diabetes, it can be a kidney disease caused by individual mechanism in the diabetic patient or it can be a coincidence of simultaneous occurrence of the two diseases. The involvement of the membrane-glucose cotransporter membrane and hyperglycemia are associated with the activation of the renin-angiotensin-aldosterone system, glomerular hyperfiltration and tubular hyperabsorption occur, which creates a particular situation that requires appropriate treatment. Whatever the mechanism, the patient's evolution is more unfavorable compared to those who have only one of the conditions [13,14]. Our study results for 35,13% of the patients, that were diagnosed with diabetus mellitus type II, found that 69.23% of them have further developed diabetic nefropathy.

In the study of Tsimihodimos V et al. [15] it was shown that lipid metabolism is disrupted in patients with CKD even in the early stages and can be very severe in some cases, further impairing kidney function. The pathogenic mechanisms are not fully understood, but studies show that dyslipidemia is a pathogenic factor for both kidney disease and the associated cardiovascular disease [16]. In our study dyslipidemia was identified in only 8,1% of the patients.

Atherosclerosis sets in early and progresses rapidly in patients with CKD. It usually increases the risk of cardiovascular disease and, as the severity of kidney disease increases, so does the mortality rate, according to Olechnowicz-Tietz S. et al. [17]. In our study population 27.02% were found to suffer from atherosclerosis.

Considering the cardiovascular risk, compared to the general population, patients with CKD, according to the study of Matsushita K et al. [16] have a constant increased cardiovascular events risk. Studies identified that 70% of CKD patients, and up to 80-90% of those on dialysis, are diagnosed with high blood pressure [18,19]. Considering all these data, our studies results that 91.9% of CKD subjects were suffering of/diagnosed with hypertensive disease are consistent with the data in the literature.

As shown in the study of Maric-Bilkan C. et al. [20], in the absence of diabetes, women have a considerably lower risk than men of vascular, microvascular or macrovascular diseases. The opposite trend is observed in diabetic patients: women are at higher risk for these complications. Microvascular lesions that occur in nephropathy, neuropathy, and retinopathy are more common in men. Macrovascular lesions consisting of chronic coronary heart disease, myocardial infarction, peripheral artery damage, and stroke are more common in women. To explain this, the focus has been on sex steroids, which play an important role in regulating heart function. Estrogens are generally considered hormones with cardioprotective effects, and androgens with adverse cardiac effects. But the effects of these hormones on the target organs are complex and different, and the presence of diabetes interferes with the pathophysiological mechanisms that cause vascular damage [14,18,19].

Renal comorbidities are, in part, primary kidney disease that has progressed unfavorably, with the patient reaching the stage of CKD that requires dialysis in order to survive [20]. Another part of these comorbidities is secondary, the pre-existing disease being another. This is the case with nephropathy, which develops during the course of hypertensive disease or diabetes [14]. The percentage of incidence of nephropathy of any etiology in the study population was 45.94%. It is a high percentage, which is explained by the fact that, as we have shown above, diabetes and hypertension are precursors or caused by CKD.

Our results are consistent with literature data showing that 11.2% of patients in a large group of with CKD present with kidney stones. The same study by Chuang TF. et al [21] shows that patients with kidney stones are 1.82 times more likely to develop CKD.

Secondary hyperparathyroidism is found in chronic dialysis patients, the incidence of this comorbidity being reduced by treatments with phosphorus chelators, calcium supplements and calcitriol. As shown in the study of Llach F. et al [22] there are situations when parathyroidectomy is necessary, namely when clinical signs such as persistent hypercalcemia, pruritus, metastatic calcifications appear [23]. In our study hyperparathyroidism was found in only 5,4% of the patients but out of the whole lot, 10.81% of the patients had already been treated with parathyroidectomy. The latter can cause insufficiency of many organs.

Blood characteristics such as blood group or different blood components (eg. lymphocytes) have been linked to chronic diseases or their treatments toxicity [24-27]. According to the study of Ueda N. et al. [28] hemoglobin levels below 12 g/dl for women and below 13 g/dl for men are considered anemia. Iron and erythropoietin deficiency causes anemia in patients with CKD. Hepcidin is a hormone produced by the liver in inflammation or when the body's iron deposits in the form of ferritin or hemosiderin are saturated. Hepcidin binds to and inhibits ferroportin, thereby decreasing the release of iron from the enterocyte and reticuloendothelial cells and decreases plasma iron. Inflammatory status in CKD increases hepcidin regardless of the availability of iron to the body, so it becomes necessary to administer iron, but also to reduce inflammatory phenomena [29]. It was a frequent occurence in our study as 62.5% of our patients were diagnosed with anemia.

Hepatitis B or C virus infections can cause chronic kidney damage but do not have a high incidence according to Chacko EC et al. [30]. If the infection occurs in patients with CKD, anti-infective treatment has many side effects and may worsens the prognosis. Similar results were shown in our study as only 10.81% of the patients presented with concurrent viral hepatitis and CKD.

CONCLUSIONS

Following the analysis of the information about the patients with CKD in the dialysis program from our study weight has been found to be significantly higher in men, compared to women. Albuminemia was within normal limits in all patients, significantly correlating with the body weight. Patients' comorbidities identified in our study were similar to the ones found in the current literature to be related to CKD. The most common comorbidity is high blood pressure, identified in over 90% of the subjects. Anemia is the second most common comorbidity, occurring in almost 60% of patients. With high frequency, in over 20% of patients, we observed the presence of diabetes, atherosclerosis, ischemic coronary heart disease, nephropathy of various etiologies, autosomal dominant polycystic disease and chronic glomerulonephritis.

Abstract: *Coronary CT angiography is a non-invasive method of analyzing the coronary lumen through which the atheromatous bur-den can be evaluated, with the analysis of the type of plaque (soft, calcified, mixed) and the impact on the arterial lumen (stenosis, occlusion). The anatomical evaluation by coronary CT is indicated in symptomatic patients with low and medium risk factors for coronary atherosclerotic disease, in those with inconclusive laboratory and EKG results, patients with un-certain stress test results, in the evaluation of coronary grafts and intrastent stenoses. Depending on the result of the angiography, the severity of the stenosis and the management of the patient are established. In the case of mild and medium stenoses, risk factors management and drug treatment are recommended. For severe stenoses, patients are referred for interventional coronary angiography or functional evaluation. Coronary CT angiography increases the certainty of coronary atherosclerotic disease diagnosis. It has a superior discriminative capacity of plaques with low attenuation, the main predictor of myocardial infarction, with almost five-fold higher risk. Coronary CT angiography increases the adaptation of medication, and the inclusion of statin therapy decreases the risk of fatal and nonfatal myocardial infarction at 5 years and increases the quality of life.*

Keywords: *coronary CT angiography, coronary atherosclerotic disease, calcium score, CAD-RADS*

INTRODUCTION

Atherosclerotic disease is the main cause of death in Europe [1]. Lifestyle factors (smoking, diet, level of physical activity) but also biological risk factors (hypertension, hypercholesterolemia, hyperglycemia) contribute to this [2].

The management of patients with coronary atherosclerotic disease is complex, including numerous investigative methods. Of these, coronary CT angiography has been analyzed more and more, over the last decade, due to technological progress. Coronary CT angiography is a non-invasive method of evaluating the heart and coronary arteries. Coronary CT angiography is performed using a computer tomograph that involves high-speed scans for moving organs and contrast material containing iodine, administered in injectable intravenous form to obtain the best images of the coronary arteries and the heart. Thus, the atheroma plaques in the coronary arteries can be identified, the type of plaques analyzed (soft, calcified, mixed), and the consequences on the arterial lumen (stenoses, occlusions) evaluated. Coronary anomalies can be detected, valve morphology can be analyzed, as well as the degree of myocardial perfusion.

MATERIALS AND METHODS

The main reference studies used in evaluating and managing patients with coronary atherosclerotic disease are extensive studies that have contributed to the current state of knowledge in this field, demonstrating the usefulness of the investigation in diagnosis, monitoring, and recommendations for the treatment of the disease.

The PROMISE study (Prospective Multicentre Imaging Study for Evaluation of Chest Pain) – from the year 2017 – showed that coronary CT angiography is a superior means of evaluation for identifying patients at risk with nonobstructive coronary atherosclerotic disease, compared to classical functional exploration means, in patients with stable angina pectoris and with an average probability of coronary atherosclerotic disease. The patients were randomly divided into two groups, 4500 patients were investigated by coronary CT angiography and 4602 patients were evaluated by functional means (exercise electrocardiogram, exercise ultrasound, and exercise myocardial scintigraphy). The patients were subsequently monitored for 26 months. The significantly lower incidence of coronary events in patients investigated by coronary CT angiography compared to those evaluated by functional means (33.4% versus 78.0%) demonstrates that coronary CT angiography had a significantly higher discriminative capacity for predicting coronary events than functional explorations (c -index, 0.72; 95% CI, 0.68-0.76 versus 0.64; 95% CI, 0.59-0.69; P=0.04) [3].

The SCOT HEART study (Scottish Computer Tomography of the Heart) is large, started in 2010, and is still ongoing, which will continue until 2027, with some of the results already published. It is a randomized parallel study, which included, between 2010-2014, 9848 participants with angina pectoris suggestive of coronary atherosclerotic disease and with mild and medium risk factors. The patients were divided into two groups that were evaluated differently: 4146 patients by coronary CT angiography and the rest were managed by standard anatomical and functional means. The main diagnostic results showed that coronary CT angiography increased the certainty of the diagnosis of coronary atherosclerotic disease (relative risk [RR] = 1.79, 95% confidence interval [CI] 1.62-1.96, p < 0.001) and reduced the frequency of the diagnosis of angina due coronary atherosclerotic disease (RR = 0.93, 95% CI 0.85-1.02, p = 0.13) compared to standard care [4]. The main clinical result was a decrease in the risk of fatal and nonfatal myocardial infarction at 5 years, which was 2.3% in the coronary CT angiography group, compared to 3.9% in the group managed by standard means. The secondary results consisted of an increase in the quality of life, the adaptation of medication, and the inclusion of statin therapy. In those cases where the lesions were severe, patients were referred for angiography and stenting [5].

Other secondary, very important results emerged in 1769 patients, followed for 4-5.7 years, which proved that the presence of plaques with low attenuation is the main predictor of myocardial infarction, independent of the presence of cardiovascular disease risk factors, of the score of calcium or area of stenosis. Patients with low-attenuation plaques had an almost 5-fold higher risk of myocardial infarction (95% CI, 2.06-10.5; P<0.001). In 41 patients who suffered an acute myocardial infarction, both low-attenuation plaque load and calcium score were increased (336 [62-1064] versus 19 [0-217] Agatston units; P<0.001), and the presence of obstructive coronary artery disease (54% versus 25%; P<0.001) [6].

The UK's National Institute for Health and Care Excellence's 2016 NICE chest pain guideline recommended coronary CT angiography as the first line of evaluation in patients with new stable chest pain. Emphasis is placed on anatomic explorations over functional ones, a choice to which cost-effectiveness also contributes [7,8].

However, this approach raised concerns that, after the first evaluation with coronary CT angiography, there would be an increased referral to further investigations, such as invasive coronary angiography. To test this, a retrospective study was conducted on 652 patients who underwent coronary CT angiography from 2017 to 2018. The results showed that 92 patients had moderate (50-70%) or severe stenosis (>70 %). Of these, 69 were directly referred for invasive coronary angiography, of which 63 underwent the investigation, and severe atherosclerotic coronary disease was confirmed in 40 patients (63%). Among the patients with moderate stenosis, 18 were referred to cardiac stress echography, which was positive in one case. The remaining patients had mild stenosis in 62 cases, 36 studies were inconclusive, and the rest of them (462 patients) were normal or had minimal stenosis [9]. The study's conclusions showed that coronary CT angiography is an effective first-line method in the evaluation of patients with newly appeared stable angina pectoris, most of them having normal results or minimal coronary atherosclerotic disease. In patients with severe stenosis, it had an increased detective capacity, the stenosis being confirmed by invasive coronary angiography in 63% of cases.

The positive predictive value for coronary stenosis of coronary CT angiography, compared with stress tests, was evaluated and published in a study from 2019. A total of 800 patients with stable angina pectoris from two centers were included, one in the UK where 400 patients were investigated with coronary CT angiography and a center in Portugal where 400 patients were investigated with exercise tests (treadmill exercise stress test EST or stress imaging test). The patients in the two groups were equally distributed in terms of gender and BMI. Of the 400 coronary CT angiographic examinations, 387 (96%) were diagnostic. Of these, 92 patients (23%) had CAD-RADS 3-5 coronary obstruction, of which 67 (72%) underwent coronary angiography and 61 patients (91%) had atherosclerotic coronary obstructive disease confirmed. In the Portuguese group, 400 patients with stable angina evaluated by stress test with the positive result, recommended for interventional angiography, were included. On interventional angiography, the obstructive coronary disease was diagnosed in 51% of patients. In conclusion, the positive predictive value of coronary CT angiography is 91%, statistically significantly higher (p<0.0001) than stress tests (51%) [10]. The study concludes that coronary CT angiography, due to its significantly higher predictive value than exercise tests, has a good indication as a first test for evaluating coronary stenosis, and could mean the avoiding of unnecessary interventional angiographic tests.

The AGATSTON coronary artery calcium score is a semi-automatic measurement of the degree of calcification of the coronary arteries. It is an investigation performed with a low dose of radiation at the beginning of the coronary CT angiographic examination, before the administration of contrast substance. The main role is an early stratification of the degree of coronary atherosclerotic infiltration.

An automatic calculation of coronary calcifications is made according to the density in Hounsfield units and the area occupied by the plaque.

Depending on the value of the total calcium score, coronary artery disease is divided into five degrees: no evidence of disease (calcium score 0), minimal damage (1-10), mild (11-100), moderate (101-400), severe (>400), the risk of major cardiac events increases in patients with an Agatston score greater than 160 (Table1) [11].

Table 1: Calcium score according to the Agatston scale

Agatston score	Coronary artery disease
0	no evidence of calcium
1-10	minimal
11-99	mild
100-399	moderate
400-999	severe
1000+	extensive calcium deposits increased risk of coronary events in the next year

The calcium score showed a good correlation with coronary CT angiography in the diagnosis of coronary plaques, with the limitation of not being able to evaluate the soft component of the plaque.

Special emphasis is given to the Agatston score of zero, there is the concept of "the power of zero", which means that patients are considered low risk and if there are no other risk factors, that leads to the avoidance of certain preventive drug therapies, such as statins. Another important role of the calcium score is personalizing the prescription of statins and aspirin among the general population but also the population with special conditions such as severe hypercholesterolemia or diabetes [12].

Coronary calcium score (CAC) has become a popular investigation due to its accessibility, speed, tolerability, low cost, reproducibility, and financial benefits due to the exclusion of complex coronary pathologies that involve more expensive investigations [13].

There are practice guidelines that include structured recommendations for the treatment and prevention of coronary atherosclerotic disease but there are some variations between countries in using coronary calcium score as a reference for inpatient treatment. However, there is a common agreement that coronary calcium scoring assessment is to begin in patients over 40 years. In asymptomatic patients with an intermediate risk of atherosclerotic coronary disease and a calcium score of over 100, the initiation of statin treatment is recommended. In patients with a calcium score of 0, the risk is decreased and the administration of statins is retained, with a repeat of the calcium score after 10 years. These conclusions were reached following the MESA study (Multi-Ethnic Study of Atherosclerosis) in which the 10-year risk of cardiac events was between 1.3-5.6% for a calcium score of 0 and 13-26.6% for a calcium score over 300. The MESA study concluded that in conditions of other cardiovascular disease risk factors maintained constant, the relative risk of cardiac events increases proportionally with the increment of the calcium score [14].

For the good management of patients with coronary atherosclerotic disease, the Guide of the European Society of Cardiology (ESC) was updated in 2019. It established coronary CT angiography as the first line of anatomical evaluation of patients with coronary atherosclerotic disease. The previous recommendations (ESC guide from 2013) proposed a combined approach between anatomical and functional means.

The current management of patients with angina pectoris and suspected obstructive coronary disease consists of a 6-step approach.

1. In the first stage, patients are evaluated through a clinical examination to identify patients with unstable angina or acute coronary syndrome, with the determination of symptoms.

2. The second step involves the evaluation of the general condition and the quality of life - patients with unstable angina or acute coronary syndrome are not included.

3. The third step includes performing some basic tests (blood tests, resting electrocardiogram, resting cardiac ultrasound) and evaluating the function of the left ventricle.

4. Step four consists of assessing the risk of clinical probability of obstructive coronary disease.

5. The fifth step involves diagnostic tests, which are chosen depending on the clinical probability of obstructive coronary disease but also multiple clinical factors, comorbidities, expertise, and access to examinations.

Thus, the anatomical evaluation by coronary CT is recommended as an initial diagnostic test in symptomatic patients in whom the coronary atherosclerotic disease cannot be excluded by clinical evaluation, in those with a low and medium probability of coronary atherosclerotic disease.

Functional tests are recommended in situations where coronary CT angiography is non-diagnostic or has shown stenoses whose functional significance is uncertain.

Invasive angiography is recommended for those with very high clinical probability, symptoms that do not respond to drug treatment, and typical angina at a low level of effort, in patients with an uncertain diagnosis on functional tests.

Coronary CT angiography is not recommended in extensive calcifications, irregular heart rhythm, significant obesity, the impossibility of performing respiratory commands, and any other situations in which qualitative images cannot be obtained.

6. The sixth step, depending on the result of the above tests, the management of the patient and the drug treatment are decided.

Severe calcifications and poor clinical images can lead to an overestimation of the severity of stenoses. In patients that present revascularization through stents and bypass grafts, the accuracy of the coronary CT angiographic examination is impaired in some cases due to the presence of blooming artifacts and the incomplete evaluation of the native vessels. Coronary CT angiography is not recommended in any situations in which qualitative images cannot be obtained: extensive calcifications, significant obesity, and the impossibility of performing respiratory commands [15].

CAD-RADS Coronary Artery Disease Reporting and Data System is a method of evaluating coronary atheromatous plaques developed by the American Cardiology Society with the main purpose of standardizing the reporting of coronary atherosclerotic disease.

Also, the method includes recommendations for patient management depending on the result of coronary CT angiography (Table 2).

Table 2: CAD Rads score for the quantification of stenoses and patient management

CAD-Rads	Stenosis	Additional test
0	0%	-
1	1-24% minimum	-
2	25-49% mild	-
3	50-70% moderate	functional evaluation
4A	70-90% in 1 or 2 vessels	functional evaluation or interventional coronary angiography
4B	>50% in the left main trunk >70% in 3 vessels	interventional coronary angiography
5	100% total occlusion	interventional coronary angiography and viability assessment
N	Non-diagnostic study	additional evaluations

Thus, stenoses are divided into 5 categories, as follows:

- CAD-RADS 0 means the absence of plaques or stenoses and implies the search for other causes of angina pectoris;
- CAD-RADS 1 are plaques without stenosis or minimal stenosis (1%-24%) and imply preventive therapy and risk factor management;
- CAD-RADS 2 includes mild stenoses (25-49%) and includes preventive therapy and risk factor management, especially in patients with non-obstructive plaques in several segments;
- CAD-RADS 3 are moderate stenoses (50-69%). Patient management consists of anti-ischemic pharmacological treatment, preventive with the treatment of risk factors;
- CAD-RADS 4 are severe stenoses, which include two sub-categories: A = severe stenoses (70-99%) and B = tri coronary stenoses (≥70%) or left common coronary trunk (>50%). For category A, interventional coronary angiography or functional evaluation is recommended and for category B, interventional coronary angiography is recommended, to which anti-ischemic drug treatment and treatment of risk factors are added;
- CAD-RADS 5 is total occlusion (100%), and interventional coronary angiography and/or viability assessment is recommended, to which anti-ischemic drug treatment and treatment of risk factors are added;
- CAD-RADS N includes non-diagnostic studies that cannot exclude obstructive coronary disease, and require additional/alternative investigation.

All vessels larger than 1.5 mm in diameter must be included in the classification.

CAD-RADS 1 category also includes plates with positive remodeling and no evidence of stenosis.

There are four modifiers of the CAD-RADS score that are mentioned in the result with the "/" symbol, these are 1 N (non-diagnostic), 2 S (stent), 3 G (graft), and 4 V (vulnerability)[16].

RESULTS

The selected studies show that coronary CT angiography increases the certainty of the diagnosis of coronary atherosclerotic disease. It can predict coronary events, decreases the risk of fatal and nonfatal myocardial infarction at 5 years, and increases the quality of life. Coronary CT angiography has a good indication for being the first test for evaluating coronary stenosis due to its higher predictive value than exercise tests, thus avoiding several unnecessary interventional angiographic tests. The management of patients with coronary atherosclerotic disease can be conducted depending on the result of coronary CT angiography. The detection of severe lesions by coronary CT angiography makes intervention possible in the next stage by angiography and angioplasty.

DISCUSSION

The indications for coronary CT angiography are numerous - from retrosternal pain, clarification of inconclusive non-invasive studies, and assessment of coronary atherosclerosis and by-passes or stents.

The management of the patient with coronary atherosclerotic disease involves a clinical examination and basic tests (blood tests, resting electrocardiogram, resting cardiac ultrasound). Anatomic evaluation by coronary CT is recommended as an initial diagnostic test in symptomatic patients with low and intermediate probability of atherosclerotic coronary artery disease. Functional testing is recommended in situations where coronary CT angiography is nondiagnostic or has revealed stenoses of uncertain functional significance. Depending on the severity of the stenosis, the management of the patient is established. For minimal and small stenoses, preventive therapy and the management of risk factors are chosen. For moderate stenoses, anti-ischemic pharmacological treatment is added, and for severe stenoses, interventional coronary angiography or functional evaluation is recommended.

Also, with the help of coronary CT angiography, other structures such as bones, soft tissues, lungs, or blood vessels can be visualized simultaneously during the scan, being useful for a possible differential diagnosis.

There are limitations of coronary CT angiography such as pregnancy or chronic renal failure, and other contraindications: cardiac arrhythmias, hyperthyroidism, and iodine allergy. In patients with revascularization through stents and bypass grafts, the accuracy of the coronary CT angiographic examination can be impaired due to blooming artifacts and incomplete evaluation of the native vessels. Coronary CT angiography is not recommended in any situations in which qualitative images cannot be obtained: extensive calcifications, significant obesity, and the impossibility of performing respiratory commands.

CONCLUSION

Numerous studies have proven coronary CT angiography as the main investigation for coronary anatomical evaluation. Coronary CT angiography provides important information about the presence and extent of coronary atheroma plaques. A major advantage is the early diagnosis of coronary atherosclerosis, based on which preventive treatment can be administered. Coronary CT angiography decreases the risk of myocardial infarction, allows drug treatment adaptation, and increases the quality of life.

Conflicts of interest and sources of funding
The authors declare no conflict of interest.
This research received no external funding.

Authors' contribution
All authors have read and agreed to the published version of the manuscript.
The respective roles of each author are: ASC first/lead author performed the research, wrote the paper, and is the corresponding author, secondary authors DC and SMS supervised the paper, implemented feedback, and conceptualized some ideas.

Ethics approval and consent to participate
The manuscripts contain a study that hasn't been performed on humans, ethical review and approval were not applicable.

Patient consent for publication
Not applicable.

Abstract: *We wanted to evaluate the efficacy of intravenous immunoglobulin (IVIG) treatment in Covid-19 patients in the intensive care unit (ICU). Sixteen (66.7%) male and 8 (33.3%) female adult severe Covid-19 patients who were treated with IVIG in the tertiary ICU between April 2020 and October 2021 at Ankara City Hospital were retrospectively reviewed. The median age of the patients was 63 (interquartile range (IQR):19). The patients were evaluated in terms of laboratory values and clinical results before and after IVIG treatment. There was no statistically significant difference between survived and deceased Covid-19 patients treated with IVIG in terms of age, gender, the onset of symptoms, presence of concomitant diseases, APACHE-II scores, duration of mechanical ventilator support, and length of stay in the ICU. When the laboratory values before and after IVIG treatment were compared, a significant decrease was identified only in alanine transaminase levels (p=0.01). However, there was a statistically significant difference in mortality in 5 patients with Guillain-Barré syndrome who all survived (p=0.001). IVIG treatment was effective in Covid-19 patients with Guillain-Barré syndrome. However, IVIG treatment did not have a statistically significant effect on pre and post-treatment laboratory values, morbidity, and mortality of severe Covid-19 patients in the ICU.*

Keywords: *Covid-19, critical care, Guillain-Barré syndrome, Intravenous immunoglobulin*

INTRODUCTION

Coronavirus disease 2019 (Covid-19) is caused by a RNA virus named Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) [1,2]. Covid-19 can lead to asymptomatic infection, mild symptoms, or severe pulmonary symptoms with hyperinflammation [3]. In severe Covid-19 patients, management of hyperinflammation and cytokine storm with appropriate antiinflammatory agents is recommended [4]. Different anti-inflammatory agents have been tried on critically ill patients during the Covid-19 pandemic.

IVIG is a biological agent which contains pooled polyclonal immunoglobulin G from the plasma of approximately one thousand healthy blood donors [1]. IVIG is used for the treatment of immunodeficiency, autoimmune and inflammatory diseases [5]. IVIG has not only anti-inflammatory effects but also the ability to neutralize bacterial toxins [6]. IVIG treatment has also been tried in epidemic diseases related to viruses such as influenza A H1N1, Middle East Respiratory Syndrome (MERS-CoV-2), and Severe Acute Respiratory Syndrome (SARS), and it has been reported that IVIG treatment decreased viral load, caused clinical improvement and decreased mortality in patients with a severe course [7,8]. In light of experience, IVIG treatment has been recommended to be used for the management of patients with Covid-19 [1,9-13]. However, the role of IVIG treatment in patients with severe Covid-19 remains unclear. Thus, this study aimed to evaluate the efficacy of IVIG treatment administered to severe Covid-19 patients in the ICU.

MATERIALS AND METHODS

Local ethics committee approval for this study was obtained from Ankara City Hospital (E2-21-835). The electronic records of 640 Covid-19 patients who were followed up between April 2020 and October 2021 in tertiary ICU were retrospectively reviewed. Thereafter, sixteen (66.7%) male and 8 (33.3%) female adult Covid-19 patients who were treated with IVIG in the ICU between April 2020 and October 2021 at Ankara City Hospital were included in this study for further analysis. The definitive Covid-19 diagnosis was based on both real-time reverse transcription polymerase chain reaction (RT-PCR) test results and ground glass appearance with pneumonia on thorax computed tomography. These severe Covid-19 patients had also respiratory distress with peripheral capillary oxygen saturation (SPO2) ≤ 93% in room air before admission to the ICU.

IVIG treatment was administered due to sepsis in 6 (25%) patients, Guillain-Barré syndrome in 5 (20.8%) patients, hematological disorders such as hemophagocytic syndrome, chronic lymphocytic leukemia and autoimmune hemolytic anemia in 9 (37.5%) patients, rheumatologic and immunological disorders such as immunodeficiency, systemic lupus erythematosus, myositis and vasculitis in 4 (16.7%) patients. In all patients, IVIG was administered at 0.4 g/kg/day for 3 consecutive days. These 24 patients were evaluated in terms of laboratory values before the first IVIG treatment session and after the third IVIG treatment session. Thus, neutrophil, lymphocyte and platelet count, neutrophil/lymphocyte ratio, lactate dehydrogenase, d-dimer, fibrinogen, ferritin, procalcitonin, c-reactive protein (CRP), interleukin-6, aspartate aminotransferase (AST) and alanine aminotransferase (ALT) values were noted. Demographic data, the onset of symptoms, concomitant diseases, APACHE II scores, duration of mechanical ventilator support, length of ICU stay, and mortality rates were also recorded.

For all statistical analysis, Statistical Packages for the Social Sciences (v17.0 SPSS 24 Inc. Chicago, IL) software was used. Categorical data were presented as numbers and percentages, while quantitative data were presented as mean standard deviation or median and interquartile range (IQR), as appropriate. The differences between the two groups were evaluated with the Mann-Whitney U test and the chi-square test. The statistical significance level was accepted as p<0.05.

RESULTS

The median age of the patients included in this study was 63 (IQR:19), and the median time to symptom onset was 6.5 days (IQR:6). The median APACHE II score of these patients was 16 (IQR:9). The median length of stay in the ICU was 22.5 (IQR:34) days, whereas the median mechanical ventilator time was 19 days (IQR:29) (Table 1). Eighteen (75%) patients had concomitant diseases such as diabetes mellitus type 2, hypertension, and coronary artery disease. The most common disease accompanying Covid-19 was hypertension in 13 (54.2%) patients. The most common symptom was dyspnea in 17 (70.8%) patients. Fever was present in 7 (29.1%) and cough in 5 (20.8%) patients. Other less frequent symptoms were headache, sore throat, nausea, vomiting, impaired taste and smell, myalgia, and weakness. Complications, which were not related to IVIG treatment, such as gastrointestinal bleeding in 2 patients, cerebrovascular accident in 1 patient, myocardial infarction in 1 patient, pneumothorax in 6 patients, and seizures in 2 patients were observed in total in 12 (50%) patients. Antibiotics were empirically administered in 15 (62.5%) of the patients. Unfortunately, 16 (66.7%) patients passed away due to complications related to Covid-19 (Table 1).

Table 1: Characteristics of the Intravenous Immunoglobulin Treated Covid-19 Patients

Characteristics of Covid-19 patients	Survived	Deceased	Total	*P* value
Gender (n, %) Male Female	 6 (75) 2 (25)	 10 (62.5) 6 (37.5)	 16 (66.7) 8 (33.3)	0.67*
Age (years) (median, IQR)	61.5 (29)	63.5 (19)	63 (19)	0.85**
The onset of symptoms (days) (median, IQR)	6.5 (3)	6.5 (6)	6.5 (6)	0.60**
Length of ICU stay (days) (median, IQR)	29.5 (42)	22.0 (23)	22.5 (34)	0.42**
Mechanical ventilator duration (days) (median, IQR)	26 (59)	16 (27)	19 (29)	0.32**
Presence of concomitant disease (n, %)	7 (87.5)	11 (68.8)	18 (75)	0.62*
Diabetes mellitus type 2	4 (50)	4 (25)	8 (33.3)	0.36*
Hypertension	6 (75)	7 (43.8)	13 (54.2)	0.21*
Coronary artery disease	-	5 (100)	5 (20.8)	0.13*
Complications (n, %)	5 (62.5)	7 (43.8)	12 (50)	0.67**
Antibiotic use (n, %)	4 (50)	11 (68.8)	15 (62.5)	0.41**
APACHE II score (median, IQR)	15 (9)	18.5 (12)	16 (9)	0.13**

*†IQR: interquartile range. ‡ICU: intensive care unit; *Chi-square test was used. **Mann-Whitney U test was used*

There was no statistically significant difference between survived and deceased patients in terms of gender, age, the onset of symptoms, length of stay in the ICU, duration of mechanical ventilator support, accompanying symptoms, concomitant diseases such as diabetes mellitus type 2, hypertension, coronary artery disease, complication development, antibiotic use, and APACHE II scores. However, a significant difference was identified in mortality when the effect of IVIG treatment administered for Guillain-Barré syndrome in 5 patients and other disorders were compared (p=0.001). All patients with Guillain-Barré syndrome survived after IVIG treatment. All 6 patients, who were treated with IVIG for sepsis, died. Three patients died and 1 patient survived with rheumatological and immunological diseases. Seven of 9 patients with hematological diseases passed away, whereas 2 patients survived (Table 1). When the laboratory values before and after IVIG treatment were compared, a significant decrease was found only in ALT levels (p=0.01) (Table 2).

Table 2: Laboratory Parameters of Covid-19 Patients Before and After IVIG Treatment

Laboratory parameters	**Before IVIG treatment**	**After IVIG treatment**	***P* value***
Neutrophil count x10^9/L	8.4 (6.5)	8.0 (7.8)	0.84
Lymphocyte count x10^9/L	0.59 (0.49)	0.59 (0.45)	0.26
Platelet count x10^9/L	206.5 (152)	210 (142)	0.48
Neutrophil/lymphocyte ratio	13.0 (10.4)	11.8 (7.0)	0.39
Lactate dehydrogenase (U/L)	456.5 (349)	459.5 (193)	0.18
D-dimer (mg/L)	2.79 (4.91)	2.69 (6.05)	0.74
Fibrinogen (g/L)	5.4 (2.9)	4.4 (2.8)	0.22
Ferritin (µg/L)	1011 (1417)	715 (1198)	0.38
Procalcitonin (µg/L)	0.30 (0.35)	0.51 (1.17)	0.10
C-reactive protein (g/L)	66 (136)	95 (151)	0.76
Interleukin-6 (pg/mL)	31.1 (34.3)	38.2 (61.4)	0.40
Aspartate aminotransferase (U/L)	44.5 (50)	40.5 (26)	0.21
Alanine aminotransferase (U/L)	52.5 (48)	34.5 (46)	0.01

*In all patients, IVIG was administered 0.4 g/kg/day for 3 consecutive days. Numerical data are given as a median and interquartile range. IVIG: intravenous immunoglobulin. *Wilcoxon test was used.*

DISCUSSION

The severity of the cases, the IVIG dose, and the time of administration should be considered when evaluating the effect of IVIG on Covid-19. In our study, the patients who underwent IVIG therapy were severe Covid-19 patients and all of the patients received IVIG treatment at the same dose and duration (0.4 g/kg/day for 3 consecutive days).

Huang et al. reported that 45 non-severe Covid-19 patients who were treated with IVIG had no benefit beyond standard therapy in terms of duration of fever, virus clearance time, length of hospital stay, and use of antibiotics [14]. However, after the initiation of IVIG therapy in Covid-19 patients, there have been several studies published reporting that IVIG treatment reduced mortality in Covid-19 patients. Gharebaghi et al. reported that 30 Covid-19 patients were treated with IVIG four vials daily for three days and the in-hospital mortality rate was significantly lower in the IVIG group compared to the control group (6 (20.0%) vs.14 (48.3%), p=0.022) [15]. Sakoulas et al. administered IVIG 0.5 g/kg/d for 3 days to 16 Covid-19 patients, reporting that patients treated with IVIG had shorter median ICU stay (2.5 vs 12.5 days, p=0.006) in addition to improvement of hypoxia compared to the control group [16]. Raman et al. reported that 50 Covid-19 patients were treated with IVIG, who had a significantly shorter hospital stay, and faster recovery with an improvement in oxygen saturation. Moreover, Raman et. al claimed that positive RT-PCR tests of Covid-19 patients treated with IVIG became negative in a shorter period compared to the control group (7 vs 18 days) [17]. Ali et al. administered each group with 10 patients with different doses of IVIG 0.15, 0.20, 0.25, and 0.30 g/kg. Even 10 of 40 participants (25%) passed away, Ali et al. reported that IVIG increased survival chances and reduced the risk of Covid-19 progression [18]. Esen et al. reported that 51 Covid-19 patients who received IVIG had prolonged median survival time and reduced CRP levels [19]. Shao et al. stated that early administration (admission ≤ 7 days) of high-dose IVIG (> 15 g per day) not only improved the prognosis but also reduced 60-day mortality in severe Covid-19 patients [20].

The latest Surviving Sepsis Campaign Guidelines did not recommend IVIG therapy for the treatment of sepsis due to the low quality of evidence from previous studies [21]. All of our 6 patients treated with IVIG for sepsis died, however, all patients with Guillain-Barré syndrome survived after IVIG treatment in this study. In addition, there are several case reports of Covid-19 patients who had neurological disorders such as acute disseminated encephalomyelitis and Guillain-Barré syndrome which were reported to be successfully treated with IVIG [22-27]. Moreover, IVIG treatment has been reported to be effective in Covid-19 related immunological diseases such as multisystem inflammatory disease, myocarditis, and Kawasaki disease [28].

However, there are several studies claiming that IVIG treatment did not affect the need for mechanical ventilation, improvement in chest tomography, and reduction in mortality in severe Covid-19 patients [29]. Tabarsi et al. administered 400 mg/kg IVIG daily for three days to 52 patients, in addition to hydroxychloroquine and lopinavir/ritonavir treatment. IVIG treatment was initiated after 3.84 ± 3.35 days of admission and Tabarsi et al. did not identify any significant difference between the IVIG and control group in terms of the need for mechanical ventilation and mortality [29]. Hou et al. reported that 113 Covid-19 patients were treated with IVIG. Patients who received IVIG had a longer hospital stay of 23.0 days (19.0–31.0) with a higher mortality rate than the control group (9 (19.1%) vs 4 (6.1%), p= 0.032) [30]. Hou et al. stated that IVIG improved neither in-hospital mortality nor the need for mechanical ventilation in severe Covid-19 patients. Liu et al. stated that they treated 421 severe Covid-19 patients with IVIG and they observed no significant differences in 28-day mortality, acute respiratory distress syndrome, acute hepatic injury, acute kidney injury, diffuse intravascular coagulation, myocardial injury, shock and invasive mechanical ventilation between the IVIG and control group [31]. Focosi et al. evaluated 2401 Covid-19 patients from 10 studies and concluded that IVIG was not associated with reduced death risk, thus the current evidence from the medical literature did not support IVIG therapy in Covid-19 patients [32]. In a recently published retrospective, multi-center cohort study of critically ill Covid-19 patients, 109 patients treated with standard therapy and 74 patients who received IVIG therapy were compared [33]. Salehi et al. reported that there was no difference in length of stay in the ICU, duration of mechanical ventilation, and mortality between standard therapy and IVIG therapy groups. Thus, Salehi et al. concluded that IVIG therapy was not beneficial in critically ill Covid-19 patients [33].

Within our study, there was no statistically significant difference in mechanical ventilation duration and length of stay in the ICU between critically ill Covid-19 patients who survived or died (p=0.32 and p=0.42, respectively). However, we did not have the opportunity to compare critically ill Covid-19 patients who received IVIG therapy plus standard treatment and only standard treatment.

Moreover, the effect of IVIG on mild Covid-19 cases requires further research. Huang et al. reported that 45 non-severe Covid-19 patients who were treated with IVIG had no benefit beyond standard therapy in terms of duration of fever, virus clearance time, length of hospital stay, and use of antibiotics [14].

In this study, laboratory parameters before and after IVIG treatment were evaluated. There was neither a statistically significant increase nor decrease in acute phase reactants such as CRP, procalcitonin, ferritin, and fibrinogen before and after IVIG therapy (p=0.76, p=0.10, p=0.38, and p=0.22, respectively.) The only laboratory parameter which had a statistically significant decrease after IVIG therapy was ALT in critically ill Covid-19 patients (p=0.01) (Table 2).

IVIG may slightly increase liver function tests. However, Chen et al. reported that IVIG was effective in alleviating hepatic ischemia-reperfusion injury in a rat model by reducing ALT, AST, IL-6, and TNF-alpha [34]. Moreover, Omma et al. reported improvement in liver function tests including ALT after IVIG treatment [3].

IVIG treatment is an expensive therapy option in developing countries. Therefore, we had to administer IVIG as a salvage therapy only to severe Covid-19 patients. Unfortunately, 16 (66.7%) of 24 severe Covid-19 patients passed away despite IVIG treatment.

IVIG therapy has the risk of several side effects such as thromboembolism, renal failure, meningoencephalitis, and anaphylaxis [35]. We have encountered no side effects during IVIG therapy in our ICU.

The main limitation of this retrospective study was the small sample size. A larger sample size will help to learn more about the positive and negative effects of IVIG therapy in Covid-19 patients. As our intensive care unit was reserved for only severe Covid-19 patients during the pandemic, this study lacked a control group. The effect of IVIG on severe Covid-19 cases requires further well-designed prospective randomized controlled studies.

CONCLUSION

IVIG treatment was effective in Covid-19 patients with Guillain-Barré syndrome. However, IVIG treatment did not have a statistically significant effect on pre and post-treatment laboratory values, morbidity, and mortality of severe Covid-19 patients in the ICU.

Abstract: *Hippo signaling has been recognized as a newly identified tumor suppressor signaling pathway that can regulate cellular processes including regeneration, cell death, differentiation, and development. Its dysregulation through overexpression of YAP (Yes-associated protein) and TAZ (PDZ-binding motif) as two main oncogenic factors of the Hippo pathway has a crucial role in several cancers. Because of the limited prognosis and therapeutic targets, further understanding of molecular pathways involved in tumorigenesis is one of the interesting issues in studies. Here, we demonstrated that some viruses, through dysregulation of the Hippo signaling pathway can be implicated in transformation, metastasis, and chemotherapeutic drug resistance in virus-related cancer and also help processes involved in the pathogenesis of viral infection such as persistence.*

Keywords: *Hippo signaling pathway, virus, cancer*

INTRODUCTION

The Hippo signaling pathway was discovered to be involved in controlling organ size and cell differentiation in Drosophila melanogaster for the first time, and it has recently been recognized as a critical tumor-suppressor network [1]. Consequently, the correlation of deregulated Hippo pathway signaling in several cancer types such as breast, liver, lung, prostate, gastric and colorectal tumors has been reported. In addition to this role, the Hippo pathway is involved in the conservation of tissue-specific stem cells, tissue renewal, and damage recovery [2,3].

The Hippo pathway is a kinase cascade that includes kinases MST1 and MST2 (also known as STK4 and STK3), large tumor suppressors 1 and 2 (LATS1 and LATS2) and adaptor proteins SAV1 (Salvador homolog 1), and MOB kinase activator 1A and 1B (MOB1A and MOB1B). MST1 and MST2 induce LATS1 and LATS2 phosphorylation, which in turn facilitates LATS-dependent phosphorylation of the homologous oncoproteins YAP (Yes-associated protein; encoded by YAP1) and TAZ (PDZ-binding motif, also known as WWTR1) that inhibit the activation of transcriptional co-activators Yorkie (Yki), YAP, and TAZ [4-6].

Hippo pathway main effectors YAP and TAZ, phosphorylation by the Hippo core complex can retain them in the cytoplasm where they expose to proteasomal degradation [7]. Since TAZ/YAP mutations rarely happen other mechanisms are more likely responsible for Hippo's relevance in cancer. Growing evidence suggests that a complex network of interactions with critical pathways can modulate YAP/TAZ activity such as TGFB, GPCR, Notch, EGFR, and angiogenesis [8].

In the case of modulation of Hippo signaling, stimulation of G protein-coupled receptors (GPCRs) associated with Gas might lead to phosphorylation of LATS and consequently down-regulation of YAP. GPCRs as integral membrane receptors activated by external ligands their binding leads to the activation of the alpha-subunits of subclasses of G proteins. In contrast, stimulation of Ga12/13-coupled GPCRs is associated with suppression of LATS and up-regulation of YAP [9,10].

Other instances of membrane receptors that reported to modulate YAP expression are the receptor tyrosine kinases EGFR and ERBB4 [11]. The EGFR ligand amphiregulin (AREG) is an important YAP target that provides a positive cycle that mediates YAP and EGFR signaling and can stimulate intensifying proliferative signals from both pathways. Also, ERBB4 as a member of the EGFR family, via interaction of YAP and possibly TEAD1 with its intracellular domain in the nucleus, demonstrated either induction of YAP activation or increase expression of YAP target genes [12].

Oncoviruses are associated with about 12% of all human cancers. People carry at least one of these oncoviruses in their life, but these infections only a small proportion of these individuals go on to develop cancer [13]. The interaction between viral factors and the host is a complex process to provide a desirable microenvironment for oncogenesis [14]. The aim of this review is the improvement of our understanding of mechanisms of oncogenesis modulation by different viruses and a better understanding of tumorigenesis that may result in more effective targeted therapy in the future. By the recent rises in viral-related carcinomas and the link between Hippo and viruses, we assessed to determine if Hippo signaling is the main target in such cancers.

HEPATITIS B Virus

In recent decades human hepatocellular carcinoma (HCC) with approximately 746,000 deaths per year, identified as the sixth most common cancer and the third leading reason for cancer-related deaths in human populations [15].

Hepatocarcinogenesis, due to several genetic and epigenetic changes which occur through different stages of the disease is known as a complex process [16]. As regards the fact that hepatitis B virus (HBV) infection has a key role in the establishment of HCC, it is important to know its proteins' roles in Hepatocarcinogenesis. HBV encoded four proteins and among these proteins, the HBV X protein (HBx) is a multifunctional protein and has a critical role in hepatocellular carcinogenesis. Multiple signaling pathways are participating in the HCC progression [17,18].

Many studies are designed to assess the molecular and cellular mechanism of HCC because finding a suitable treatment for HCC is an immediate task for healing patients suffering from HCC. Recently, numerous researches have shown the role of the Hippo pathway in organ size control, cell proliferation, cell death, and tumor progression [19,20]. Although the role of YAP, which is a downstream factor of the Hippo signaling pathway in HCC, remains unclear, this review provides a vision for the regulation of YAP upstream and downstream effectors involved in hepatic cancer [21].

Interestingly, the hyperexpression of YAP can result in epithelial-to-mesenchymal transition (EMT) and may inhibit apoptosis, growth factor-independent proliferation, and anchorage-independent growth [22]. The liver has an amazing characterization that can lead to having unique features such as Growth control which in the liver has some unusual features. The liver has been known for its noticeable capacity to renew consequently to a two-third partial hepatectomy (PHx) or injury. The natural liver in an adult is composed of two parenchymal cell types — hepatocytes and cholangiocytes [23].

Dedifferentiated hepatocytes as multipotent stem cells are capable to be the source of tissue renovation in the damaged liver [24]. Factors of the Hippo signaling pathway including MST1 and MST2 have been demonstrated to have key roles in adjusting or restricting liver progenitor cells. Thus, it is predicted that the Hippo can be involved in the suppression of stem/progenitor cell proliferation in the mature liver [25]. Furthermore, some studies also showed that knocking out YAP resulted in hepatocyte and cholangiocyte injury and loss [26].

In synergy with the functional roles of Hippo signaling, any change of upstream effectors of the hippo pathway like Mst1/2 can result in over-proliferation and sometimes Hepatocarcinogenesis. Since HBV is commonly the major reason for HCC; YAP possibly has an important role in its carcinogenesis. Interestingly, YAP expression is frequently shown to be increased in HBV infections resulting in HCC, infected cell lines, and HBx transgenic mice. Through the CRE-dependent HBx attaching to the YAP promoter, HBx can increase YAP and follow stimulate YAP target genes which leads to the proliferation of hepatoma cells. Findings revealed the importance of the Hippo signaling pathway in cancer and suggested new treatments for HBV-infected patients to inhibit progression to HCC [27].

Studies have revealed that the loss of Mst1/2 may result in the promotion of several tumors in the liver of mice. The loss of both Mst1/2 is required to affect the liver since the loss of Mst1 or Mst2 is not effective on liver size or the number of liver tumors [28]. These findings firmly revealed the effect of Mst1/2 on YAP activity. Interestingly, lack of YAP phosphorylation and impairment of Mst1/2 activity that occurs in carcinogenesis have been reported in 30% of HCCs [29].

The liver-specific NF2/merlin inactivation may lead to an increase in hepatic stem cell number with a lack of any changes in differentiated hepatocytes [30]. The studies on Sav or Mst1/2 positive livers for assessment of the effectiveness of

YAP/TAZ and Lats1/2 phosphorylation in the hippo pathway displayed complex results regarding the need for Mst1/2 or Sav in Lats1/2 phosphorylation [29,31] and since in mouse fibroblasts, for YAP phosphorylation, presence of Mst1/2 was not crucial, it is considered that the pathway may be specific in hepatitis [29].

In a study on transgenic mice, it was shown that YAP induction can lead to abnormal hepatocyte expansion after 2 months and consequently several nodes have been reported in hepatitis [32]. The nodes were reported to be a collection of hepatocytes in a generative condition that condensed the near parenchyma and revealed severe HCC. Also, this liver-specific loss of either Mst1/2 in hepatocytes leads to noticeable liver growth because of its deregulated cell proliferation [28].

On the other hand, when transgenic mice models with YAP hyperactivity crossed with mice lost its DNA-binding domain TEAD2 do not promote HCC. Lacking YAP overexpression may lead to having mice with livers deficiency in Nf2/merlin after crossing with mice that have the defective TEAD2 gene, confirming the therapeutic concept of using the TEAD with YAP in the complex. Verteporfin injection has been demonstrated to reduce liver mass in YAP transgenic animal models and also has no side effect on the wild mice tissue homeostasis, defining the potency of compounds for therapeutic administration in patients with HCC. Verteporfin displayed numerous important features that make its clinical execution for HCC promising [32].

In HCC cell lines induction of YAP results in further resistance to doxorubicin-induced apoptosis; while, inhibition of YAP expression by RNA interference has been reported to reverse YAP-increased chemoresistance. These processes are mediated by the MAP kinase signaling pathway induction rather than an AKT-dependent mechanism of chemoresistance [33]. This process of chemoresistance occurs after treatment by the MEK1/2 suppressor U0126 before doxorubicin injection, which noticeably reduces cell vitality in YAP overexpressing HCC lines [34].

Survivin is accepted as an antiapoptotic protein and in HCC patients identified to be associated with a weak prognosis. Recent studies have shown YAP overexpression is in associate with survivin induction in patients with HCC. It seems that YAP has this oncogenic capacity on the cell with a survivin increase leading to carcinogenesis [35].

HUMAN PAPILLOMAVIRUS

Cervical cancer considers the most important cancer in women because it is the fourth leading reason of cancer-related death in women. Due to the detection of human papillomavirus (HPV) DNA in the majority of cervical cancer patients, high-risk HPV types recognize as the cause of cervical cancer [2].

In a study by Chunbo He et al results implicated that YAP1, one of the main oncogenic effectors of the Hippo pathway, was (11%) amplified several times, whereas LATS1/2, MST1, and FATs, that identified as upstream tumor inhibitors of the Hippo pathway, were not detectable or mutated in cervical cancer patients. YAP1 induction in cervical cancer cells noticeably triggers the expression of EGFR and its related ligands AREG and TGFa. On the other hand, TGFa and AREG, through EGFR signaling, can block the Hippo pathway and induce YAP protein (dephosphorylated LATS1, MOB1, and YAP1) to promote cervical cancer cell growth. Recognition of this circumstance between Hippo/YAP and EGFR in human cervical cancer provides an opportunity to combine targeting of the Hippo/YAP and EGFR pathways to have an efficient way to treat cervical cancer [36].

In addition, hyperactivation of YAP1 can be an important mediator to the persistence of HPV infection. First, studies report that hyperactivated YAP1 increases the expression of HPV receptor molecules such as ITGRA6, SDC1, and EGFR, which through the early stage of HPV infection can help the HPV entry process. Second, is that hyperactivation of YAP1 in cervical epithelial cells may reduce viral pattern recognition by the innate immune system. Some studies report that TLR2 and TLR4 and adaptor proteins MYD88 and TRIF were suppressed, which could facilitate HPV infection. Third, there is evidence that ectopic expression of YAP may suppress the activation of transcriptional factors that are essential for the production of type I IFNs, including IRF1, IRF3, and IRF7, leading to the reduction of IFNA1, IFNB1, and IFNE in hers. IFNs can activate antiviral factors of the immune system and play their role in the progress of innate and adaptive immune responses. Also, some studies showed that the expression and activation of main components of the type I IFN pathway, like IFNAR2, STAT1, JAK1, and IRF9, are suppressed by the expression of YAPS127A in the epithelium of the cervix. Suppression of the IFNAR2/JAK1/STAT1 signaling pathway leads to decreasing of antiviral ISGs, such as MX1, CH25H, and IFITMs (blockers of virus entry), and APOBEC3G, OAS1, ISG15, and IFI44L (suppressors of virus translation and replication) [37].

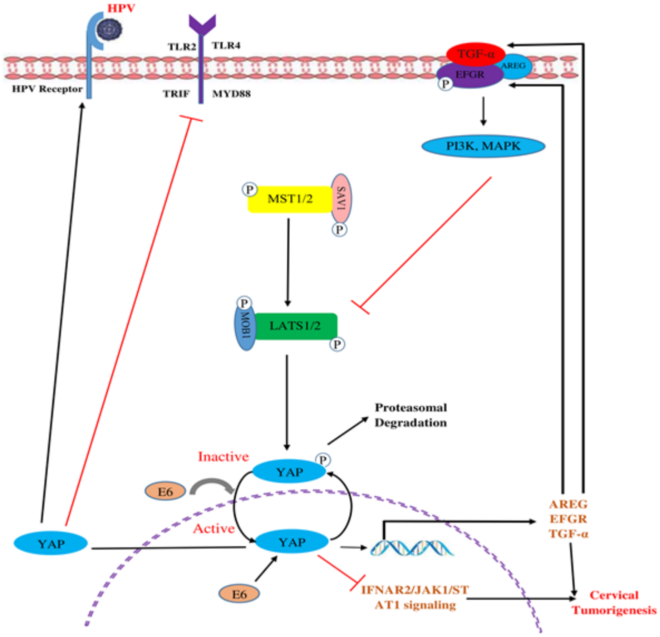
The HPV oncoproteins E6 and E7 expression can result in the suppression of some essential tumor inhibitors such as TP53 and RB1 in many types of cells [38,39]. Suppression of TP53 and RB1 extends cell life (by inhibition of death) and may lead to immortality in cervical epithelial cells, facilitating malignancy of HPV-infected cells by an oncogenic signal (including hyperactivation of YAP1) [40,41].

In epithelial cell cultures, cell-cell contact development is a key step in differentiation before the formation of distinguished apicobasal surfaces. The transcriptional co-activator YAP plays a key role in this event [42,43]. Numerous reports have shown that cell-cell contacts activate the LATS1/2 serine/threonine kinases which can phosphorylate YAP [44,45]. During phosphorylation, YAP restricts from the nucleus and it inhibits the transcription of key genes in the cell cycle [42,46]. A cervical cancer study recently demonstrated that in high-grade cervical lesions levels of nuclear YAP are increased [47].

There are some studies demonstrating that HPV16-E6 or HPV16-E6/E7 double-transgenic mice treated with estrogen may promote cervical cancer [48,49]. Related to that result, other studies report that YAP was increased in the E6 and E6/E7-induced cervical tumor cells, and YAP was localized in the nucleus of these cells [36]. The human foreskin keratinocyte(HFK) "raft" culture infected with HPV16 makes a unique model for the assessment of the HPV16 proliferation cycle [48,50].

YAP can be inactivated by two mechanisms: first, the Ser127 phosphorylation-mediated spatial adjustment (system of nuclear-cytoplasmic shuttling); and second, the Ser397 (Ser381 in YAP protein isoform 2) phosphorylation-mediated adjustment (the phosphodegron-induced degradation). These two mechanisms are applicable directly to prevent YAP oncogenic activity [51,52]. It has been observed that CK1d/ε and SOCS6 proteins are crucial for YAP degradation [52,53]. Although expression of HPV E6 in HT3 cells causes a noticeable increase in CK1d/ε and a reduction in p-YAP (S397), it suggests that the CK1d/ε pathway may not participate in the HPV E6-mediated YAP protein turning [40]. HPV E6 increases YAP protein levels, but also it upregulates the expression and activation of AREG protein in the cell culture. These observations showed a possibility that HPV E6 protein may be associated with the Hippo-ERBB signaling circle and also implicating the transformation and development of cervical cancer. Interestingly, HPV16 E6 and E7 could transcriptionally activate EGFR expression [40,54]. The HPV16 E6 makes receptor protein tyrosine kinase to signaling and facilitates the internalization of phosphorylated receptors [55] (Figure 1).

Figure 1: Schematic presentation of reciprocal interactions between HPV and Hippo signaling pathway



POLYOMAVIRUSES

Through identification of SV40 tumorigenesis in specific laboratory animals and transforms several types of cultured cells offered an opportunity to discover the molecular basis of the tumor. Viral oncogenes were introduced as key tools in the recognition of tumor inhibitor pathways in human primary cells. The p53 and p16/pRb tumor inhibitor pathways have been introduced as targets of SV40 large T. Hahn's study indicates a transformation model [56], expressed HRas V12, and a construct encoding SV40 large T to target the p14ARF/p53 and p16INK4A/pRb pathways. Recently it is discovered that SV40 small T (ST) (encoded in the large T construct) is needed without requiring large T to enhance anchorage-independent growth [57].

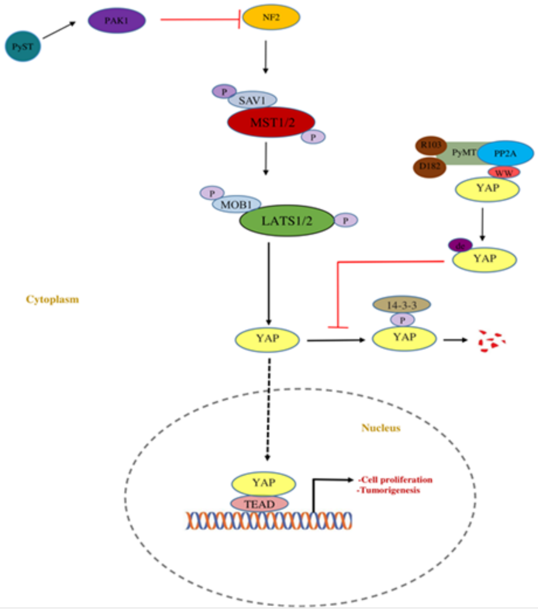
Murine polyomavirus also has frequently presented visions into tumorigenesis by demonstrating important modulation mechanisms including tyrosine phosphorylation and phosphoinositide 3-kinase (PI3K) signaling. Previous studies showed that polyomavirus small T antigen (ST) associates with YAP, an effector of the Hippo pathway, to modulate differentiation. Other studies introduced YAP as a target of middle T antigen (MT) required for transformation [58,59]. Wild-type MT via a surface containing residues R103 and D182 binds to the YAP WW domains. Mutation in each one of R103 or D182 of MT disrupts YAP binding. This happens without disturbing bindings to other signaling factors or the strength of PI3K or Ras signaling. One of the other genetic disruptions of MT binding to YAP or stopping of YAP via short hairpin RNA (shRNA) decreased MT transformation, offering that YAP has an important participation in the transformed phenotype. MT targets YAP via triggering signaling pathways that affect it and consequently bind to it. The signaling of either wild-type MT or the YAP associate MT mutant develops YAP phosphorylation at S127 and S381/397 (YAP2/YAP1) [58]. In addition to previous roles of these phosphorylated serines, MT signaling results in the reduction of YAP from the nucleus and degradation. When MT Binds to YAP, it associates YAP with protein phosphatase 2A (PP2A), resulting in the YAP dephosphorylation together with the MT complex. Furthermore, this process results in the increase of YAP in membranes. Overall, these data demonstrate that YAP develops MT transformation by mechanisms that may be due to YAP's established major transcriptional activation functions [60].

The capability of ST to discuss anchorage-independent growth brings with it its ability to inactivate the PP2A function. Suppression of PP2A may bypass the need for ST in cellular transformation models, and mutations inactivating PP2A subunits have been recognized in tumors [61,62]. PP2A has several substrates including, AKT, b-catenin, and c-Myc which are defined to be activated by ST. Although the total overexpression of these proteins only incompletely replaced ST in cellular transformation, it suggests that undefined PP2A effector pathways may be involved [62].

Hippo/MST kinase acts by a membrane-associated complex including the tumor inhibitor NF2/Merlin [63]. MST kinases enhance activating LATS kinases, which subsequently phosphorylation of the transcriptional coactivators YAP and TAZ, resulting in their inactivation of them via cytoplasmic isolation and increased degradation [64-66]. Suppression of YAP and TAZ restricts proliferation and triggers apoptosis [67].

Interestingly, it is observed that overexpression of YAP is enough to result in tumorigenesis in mice. Both SV40 ST and the Merkel cell polyomavirus ST induce endogenous YAP. Some studies provide data that ST acts through PAK1 to inactivate the NF2 tumor suppressor to alleviate the inactivation of YAP. Activation of PAK1 at the cell membrane is sufficient to bypass the requirement for ST. Restricting PAK1 activity disrupts the transforming capability of the ST protein. Therefore, ST detaches YAP from modulation via the Hippo tumor inhibitor pathway. Induction of Active YAP is required and enough to replace ST in cellular transformation. Therefore, the YAP proto-oncogene is an important mediator of the transforming properties of the ST oncoproteins [68] (Figure 2).

Figure 2: Schematic presentation of reciprocal interactions between Polyomaviruses and Hippo signaling pathway



EPSTEIN-BARR VIRUS

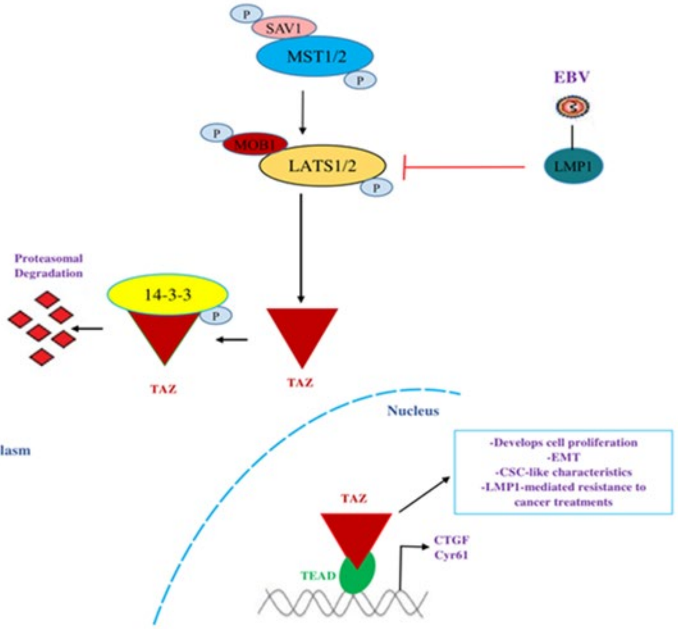
Epstein-Barr virus (EBV) is recognized as a linear dsDNA virus and a member of the human gamma-herpesvirus family that observed to correlate with various B-cell lymphomas, such as Burkitt's lymphoma, Hodgkin's lymphoma, and other tumors like nasopharyngeal carcinoma, T-cell non-Hodgkin lymphomas, and gastric carcinomas. These cancers are firmly correlated with latent Epstein-Barr virus (EBV) infection, genetic factors, and environmental factors thus EBV can regulate mechanisms affecting carcinogenesis, proliferation, death, migration of cells, epigenetic changes in lymphocyte-specific development, and induce cell immortalization. The main mechanisms related to the carcinogenic effectors of EBV consist of LMP1, LMP2, and microRNA that we will introduce bellow [69-71].

The capacity of LMP1 to immortalize and transform cells possibly depends on simultaneously regulating cellular signaling pathways which suppress apoptosis or mediate proliferative, growth factor-like effects. Furthermore, LMP1 can induce a cancer progenitor cells (CPC)-like appearance in epithelial cells, offering that LMP1-induced phenotypic alterations can be related to the promotion of cancer [72]. Therefore, the mechanism and role of LMP1 in immortalizing and transforming cells is complex and several important questions remain to be answered.

Previous studies demonstrated that LMP1 could induce actin remodeling [73]. The actin cytoskeleton is a key factor for the modulation of the Hippo pathway. These data make us investigate How LMP1 can upregulate TAZ expression by inhibition of the Hippo pathway. In a study, findings determined that the LMP1-targeted CNE1-LMP1 cells decreased TAZ expression. The target genes of TAZ are CTGF and Cyr61. Other researches demonstrate that LMP1 can trigger the mRNA expression of CTGF and Cyr61 [74]. There is the possibility that TAZ may be involved in the positive modulation of cell proliferation and survival associated with the obtaining of cancer stem cell (CSC) properties and epithelial-to-mesenchymal transition (EMT) [75, 76]. Previously, some studies have been done to determine if LMP1 can develop EMT by TAZ and define if the morphology alters. The result of these studies has shown some morphological variations from epithelial to mesenchymal phenotypes. LMP1 can develop cell proliferation, EMT, and CSC-like characteristics by TAZ and give us some visions and rationales for the LMP1-mediated resistance to cancer treatments [74].

On the other hand, it has been shown that phosphorylation of the WW domain of the transactivator TAZ by activated LATS1/2, leads to TAZ degradation [77]. Studies have shown that LMP1 can elevate the level of TAZ and increase TAZ nucleus translocation. Thus, it is possible that LMP1 could suppress LATS1/2 activation, resulting in the enhancement of TAZ stability [74] (Figure 3).

Figure 3: Schematic presentation of reciprocal interactions between EBV and Hippo signaling pathway



KAPOSI'S SARCOMA-ASSOCIATED HERPESVIRUS

Kaposi sarcoma-associated herpesvirus (KSHV) is a double-stranded linear DNA virus of the human gamma-herpesvirus family from rhadinovirals and also an oncogenic virus that is responsible for human Kaposi sarcoma (KS) and is associated with an AIDS-defining malignancy. One of the main viral proteins of KSHV is a viral G-protein-coupled receptor (vGPCR). KSHV encodes vGPCR which is essential for the initiation and progression of Kaposi sarcoma [78-80]. Previous studies identified that YAP/TAZ, two homologous oncoproteins that can be suppressed by the Hippo tumor inhibitor pathway, activates in KSHV-infected cells in in vitro conditions, KS-like tumors in mice, and clinical human KS samples [81].

The molecular process to which vGPCR contributes in KSHV-induced oncogenesis remained uncertain but it is suggested to be involving both direct and paracrine oncogenic effects, that are activated by growth factors including VEGF and PDGF induced by vGPCR [82,83]. The KSHV protein (vGPCR) activity is via Gq/11 and G12/13 to suppress the Hippo pathway kinases Lats1/2, enhancing the activation of YAP/TAZ. Also, clearance of YAP/TAZ inhibits vGPCR-induced cell proliferation and tumorigenesis in a xenograft mice model. The transformation of cells mediated by vGPCR is sensitive to pharmacological blockers of YAP [84,85].

It is demonstrated that the Knockdown of YAP or TAZ can inhibit the vGPCR-induced CTGF expression, offering that YAP/TAZ enhances the biological functions of vGPCR. In addition to the Hippo pathway, studies have shown other signaling pathways that have also been related to the oncogenic effect of vGPCR [85]. For instance, PI3Kγ is activated by vGPCR and has a key role in vGPCR-induced sarcomas, whereas NFkB has an indirect role in vGPCR-induced paracrine neoplasia. It seems the activation of YAP/TAZ is associated with other vGPCR downstream signaling events, including PI3K and NFkB, which generally participates in KS tumorigenesis in KSHV-infected patients. It is noticeable that YAP/TAZ also upregulates the expression of several growth factors, including CTGF and insulin-like growth factor (IGF) [86,87], that can be associated with neoplasia caused by vGPCR in a paracrine condition [81, 88].

Some studies revealed that Hippo pathway activation has a key role in the promotion of the lytic cycle and transition from latency. Inactivation of the Hippo pathway modulator YAP1 may promote reactivation from latency, lytic protein increase, and production of infectious virions. Interestingly, expression of the YAP1-inactivating kinase LATS1 consequently induces reactivation from latency. Conversely, LATS1 silencing decreases viral protein expression along the late phase of lytic replication. However the detailed mechanism of switching of KSHV latent/lytic by the Hippo signaling pathway is still unclear, increased amounts of nuclear centers containing the viral latency-associated nuclear antigen (LANA) have been reported in YAP1-silenced cells [89] (Figure 4).

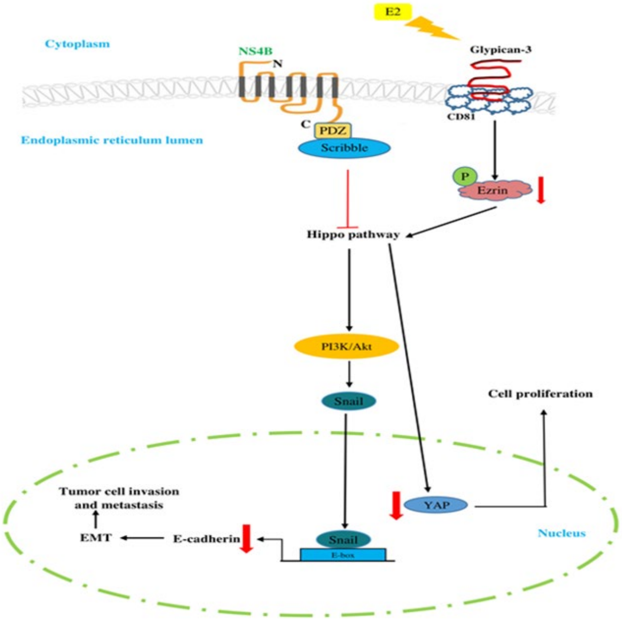
HEPATITIS C VIRUS

Hepatitis C virus (HCV), a member of the Flaviviridae family, is an enveloped RNA virus with a positive sense single-strand RNA genome [90]. Chronic HCV infection is one of the main risk factors for disease progression to metabolic disorders, fibrosis, cirrhosis, and HCC [91]. Epithelial-to-mesenchymal transition (EMT) is a physiological process by which epithelial cells lose their cell polarity and cell-to-cell junctions, and achieve migratory and invasive properties to become mesenchymal cells [92]. Previous literature reviews have shown that EMT plays a crucial role in promoting metastasis in various human cancers including HCC [93]. During the process of EMT, loss of epithelial markers, especially E-cadherin is mediated by transcriptional repressor SNAIL that binds to the E-box motif on the promoter region of E-cadherin [94]. HCV non-structural 4B (NS4B) protein is a 27kDa hydrophobic protein that role in HCC pathogenesis mediate interaction networks with cellular host proteins [95]. A study recently showed that interaction NS4B with scribble protein, a scaffold protein involved in regulating cell polarity and cell proliferation in epithelial cells, suppresses the Hippo signal pathway that subsequently results in the induction of the PI3K/AKT pathway. Induction of the PI3K-Akt pathway upregulates Snail expression via translocation to the nucleus. Finally, the up-regulation of Snail induces EMT progression by reducing E-cadherin expression which contributes to HCV-caused HCC progression, invasion, and metastasis [96].

HCVs entry to hepatocytes is recognized to be mediated by CD81 [97]. Ezrin is a member of a membrane-cytoskeleton linking protein that increases in HCC and is identified in correlation with malignant HCC [98]. In normal hepatocytes, CD81 overexpression results in the phosphorylation of ezrin and increasing nuclear YAP. As the CD81-SYK-ezrin complex causes signals to modify cell construction through protein interactions, gene expression is mediated by YAP via downstream regulation of the Hippo signaling pathway [99]. Also deregulation of the Hippo signaling pathway and increased YAP activity have been demonstrated in 50% of HCC cases [100]. In contrast since Glypican (GPC)-3 is one of the main ligands for CD81, it upregulates the expression of CD81 in HCC cells enhances activation of Hippo, a reduction in ezrin phosphorylation, and a reduction in YAP. Interestingly HCV E2 protein mimics the function of GPC3, enhances the activation of the Hippo signaling pathway, and subsequently reduces YAP and cell proliferation. Consequently, although any hepatocytes which have missing CD81 expression are considered to be resistant to HCV infection but can expand faster than the normal hepatocytes, loss of CD81 is a usual event in the promotion of hepatic neoplasia [101] (Figure 5).

Figure 5: Schematic presentation of reciprocal interactions between HCV and Hippo signaling pathway



CONCLUSION

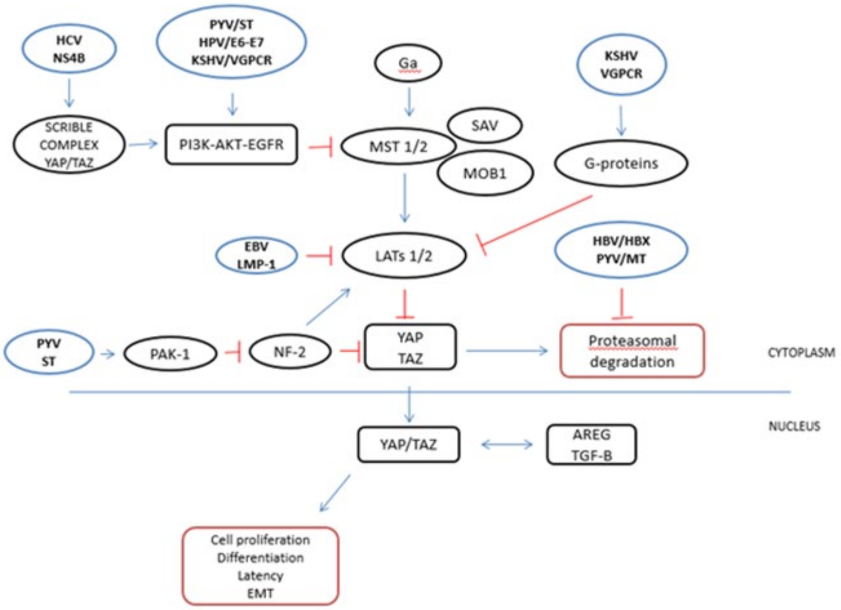
The Hippo signaling is an emerged evolutionarily conserved tumor suppressor pathway that regulates proliferation, apoptosis, differentiation, and development, whose dysregulation overexpresses YAP and TAZ as two major oncogenic downstream effectors of Hippo pathways that play a crucial role in multiple human pathological diseases, such as cancer (Table 1).

Table 1: The summary of the deregulation of the hippo signaling pathway by oncoviruses

Virus	Viral protein	Component of hippo signaling	Mechanism/Effect	References
HBV	HBx	YAP	HBx can increases YAP via the CRE-dependent HBx binding to the YAP promoter and following stimulation of YAP target genes	[27]
HPV	-	YAP1	Hyperactivation of YAP1 can be an important mediator in the persistence of HPV infection	[37]
	-	YAP1	Hyperactivation YAP1 increases the expression of HPV receptor molecules such as ITGRA6, SDC1, and EGFR	[37]
	-	YAP1	Hyperactivation of YAP1 in cervical epithelial cells may reduce viral patterns recognition TLR2 and TLR4 and adaptor proteins MYD88 and TRIF of the innate immune system	[37]
	-	YAP1	Expression of YAP may suppress the activation of transcriptional factors that are essential for the production of type I IFNs, including IRF1, IRF3, and IRF	[37]
	E6/E7	YAP	Expression and activation of main components of the type I IFN pathway, like IFNAR2, STAT1, JAK1, and IRF9, suppressed by expression of YAPS^{127A}	[37]
		YAP	YAP was increased in the E6 and E6/E7-induced cervical tumor cells and YAP was localized in the nucleus of these cells	[36]
PyVs		ST YAP	Polyomavirus small T antigen (ST) associates with YAP, an effector of the Hippo pathway, to modulate differentiation	[58]
		MT YAP	MT Binds to YAP, it associates YAP with protein phosphatase 2A (PP2A), resulting in the YAP dephosphorylation together with the MT complex	[60]
		ST YAP	ST acts through PAK1 to inactivate the NF2 tumor suppressor to alleviate the inactivation of YAP	[68]
EBV		LMP1 TAZ	LMP1 can upregulate TAZ expression by inhibition of Hippo pathway proteins	[74]
		LMP1 TAZ	LMP1 can develop cell proliferation, EMT, and CSC-like characteristics by TAZ	[74]
		LMP1 LATS1/2	LMP1 could suppress LATS1/2 activation, resulting in the enhancement of TAZ stability	[74]
KSHV		vGPCR Lats1/2	The KSHV protein (vGPCR) activity is via Gq/11 and G12/13 to suppress the Hippo pathway kinases Lats1/2, enhancing the activation of YAP/TAZ	[85]
		vGPCR YAP/TAZ	Activation of YAP/TAZ is associated with other vGPCR downstream signaling events, including PI3K and NF-kB	[86,87]
		- YAP1	Inactivation of the Hippo pathway modulator YAP1 may promote reactivation from latency, lytic protein increasing, and production of infectious virions	[89]
		LATS1	Expression of the YAP1-inactivating kinase LATS1 consequently induces reactivation from latency	[89]
HCV	*NS5B*	-	*Interaction NS4B with scribble protein suppresses the Hippo signal pathway that subsequently resulting in the induction of PI3K/AKT pathway*	[96]
	E2	YAP	HCV E2 protein mimics the function of GPC3, enhances the activation of the Hippo signaling pathway, and subsequently reduces YAP	[101]

The activation of YAP and TAZ contributes to cancer initiation, metastasis, and anticancer drug resistance via interactions with several signaling pathways in many human tumors. Oncoviruses either directly or indirectly by modulating a variety of cellular signaling pathways lead to the dysregulation of the Hippo signaling pathway to increase the expression of the downstream effectors TAZ and YAP which can be implicated in transformation, metastasis, and chemotherapeutic drug resistance in virus-related cancer and also to facilitate some processes involved in the pathogenesis of viral infection such as entry, persistence, escape from the immune system, and latency. However, in some cases inactivation of YAP can aid the pathogenesis of KSHV and HCV. (Figure 6).

Figure 6: Schematic presentation of reciprocal interactions between oncoviruses and Hippo signaling pathway



With these interpretations, we recommend that the overexpression of the major downstream effectors of the Hippo pathway, TAZ, and YAP can be used as prognosis markers in cancers caused by oncoviruses. Overall, Hippo signaling is a new pathway in viral infection, and in this way, better understanding interaction between oncoviruses with Hippo signaling can be used as a new therapeutic target in virus-caused cancers.

Abstract: *Improving the mental health of nurses and investigating the factors affecting it leads to the improvement of job performance and the quality of nursing care. Aim: The present study aimed to determine the relationship between mental health, life satisfaction, and job satisfaction of nurses in Ilam city in 2022. The present correlational study was carried out on 160 nurses working in educational hospitals of Ilam city and was selected by stratified random sampling in 2022. A four-part questionnaire was used: the first part included a question on demographic information. Minnesota Satisfaction Questionnaire (MSQ) (1977), Diener et al.'s Satisfaction with Life Scale (SWLS) (1985), and Derogatis et al.'s Symptom Checklist-90 (SCL-9) (1973) were included in the second, third and the fourth parts, respectively. Results showed no significant relationship between the total score of mental health and the total score of job satisfaction. There was a significant relationship between the total job satisfaction score and life satisfaction score (r=0.267, p=0.001). There was also an inverse and significant relationship between the total mental health score and the life satisfaction score (r=0.294, p=0.001). The collected data was analyzed using descriptive tests (frequency, mean percentage, and standard deviation) and non-parametric Spearman and Kruskal-Walli's correlation tests in SPSS ver. 22. P-value<0.05 was considered as the significance level in all tests. Job satisfaction is effective in creating motivation, efficiency, responsibility, and social accountability in the personnel of any organization. Job dissatisfaction can lead to complications such as job burnout, illness, absenteeism, the job left, leaving many nursing jobs, and the reluctance of the young workforce to attend the wards. Therefore, it is necessary to make further efforts in this field by healthcare policymakers.*

Keywords: *mental health, life satisfaction, job satisfaction*

INTRODUCTION

Mental health has an expanded definition. But every person who can deal with his/her deep issues, get along with him/herself and others, and can face his/her inevitable internal conflicts, and does not isolate him/herself from society, can be stated to have mental health [1-4]. Nurses are directly related to all social strata and touch people's problems closely. This close relationship doubles their serious responsibility toward people's health [5]. Nursing is one of the most stressful professions so the National Institute for Occupational Safety & Health has introduced it among the top 40 stressful professions [6].

There are many sources of occupational stress in the nursing work environment. Overwork, urgency, patient death, independent practice, lack of social support, poor job fit, lack of necessary specialized knowledge, unsafe workplace and rapidly changing healthcare environment are known as nursing stressors [7]. Nurses are prone to health threats in different dimensions due to long work shifts and the resulting fatigue. Nurses with no good general health are not able to provide good care such as physical and psychological support to patients. This increases the risk of mistakes and occupational accidents, and subsequent consequences affect the patient and the nurse [8].

Nurses' stress and fatigue can affect the vital and critical aspects of their performance, including problem-solving ability, decision-making ability, and creativity, and ultimately lead to disruption in medical care. Because patient safetyو health and recovery depend on the safe and optimal performance of nurses [9]. Many researchers have confirmed that job-related stress can have harmful effects on the physical and mental health of individuals [10,11]. Job stress is one of the factors affecting the health of employees. Employees' health is at risk when they face various stressors. This issue is more evident in the nursing profession [12]. The impact of job dissatisfaction on the mental health of employees has been a public concern in various societies, especially in recent years. Perceived impacts of job dissatisfaction on people's mental health from an economic point of view is also an important issue and play an important role in the quality of professional and personal life of nurses [13].

Another variable that plays a key role in improving nurses' mental health is life satisfaction. Life satisfaction is one of the mental health-related factors and refers to a person's general attitude and evaluation toward life as a whole [14]. It also reflects the balance between a person's aspirations and his/ her current situation. The greater this balance, the greater the life satisfaction will be [7]. According to previous studies, this concept is in full interaction with health and there is a close relationship between physical and mental health with life satisfaction [15]. Lyubomirsky believes that people who have higher life satisfaction, use more effective and appropriate coping methods, experience deeper positive emotions and feelings and have higher general health [16]. Nurses are among the vulnerable employees of society, whose health and balance in their personal and family life is related to occupational variables. Work-family conflict causes psychological symptoms such as higher stress, depression, chronic physical problems, increased physical complaints, lower life satisfaction, low quality of family life, and low energy levels [17]. Suzuki et al. stated that nurses were in 27th place in the evaluation of 130 stressful jobs sorted according to their reference to doctors for health problems [18].

Improving the mental health of nurses and investigating the factors affecting it leads to the improvement of job performance and the quality of nursing care. Since nursing is one of the sensitive professions and nurses spend an important part of their lives with people and patients, their mental health leads to optimal job performance and guarantees the health and improvement of many patients and people [19].

Having job satisfaction, life satisfaction and mental health leads to an improvement in the quality of patient care and increasing productivity and improving nursing services, therefore, conducting relevant studies and using their results in various aspects of the nursing profession can have useful results in care, education, management, therapy and also the personal life of a nurse [20]. Therefore, the present study aimed to determine the relationship between mental health, life satisfaction, and job satisfaction of nurses in Ilam city in 2022.

MATERIALS AND METHODS

The present correlational study was carried out on 160 nurses working in educational hospitals of Ilam city and was selected by stratified random sampling in 2022. Inclusion criteria included working in one of the above-mentioned educational hospitals and having informed consent to participate in the study. Failure to complete one of the questionnaires, an incomplete questionnaire, and unwillingness to cooperate were among the exclusion criteria. A four-part questionnaire was used: the first part included a question on demographic information. Minnesota Satisfaction Questionnaire (MSQ) (1977), Diener et al.'s Satisfaction with Life Scale (SWLS) (1985), and Derogatis et al.'s Symptom Checklist-90 (SCL-9) (1973) were included in the second, third and the fourth parts, respectively. Demographic information of nurses included age, gender, years of work experience, marital status, education level, hospital, ward, position, income level, employment status, number of children, and home type.

Minnesota Satisfaction Questionnaire (MSQ) consists of 19 items and 6 subscales of the payment system, type of job, achievement opportunities, organizational atmosphere, leadership style, and physical conditions. MSQ is scored based on a 5-point Likert scale, ranging from "Completely Disagree" (Score 1) to "Completely Agree" (Score 5). To calculate the overall score of the questionnaire, the scores of all the items are added together. Scores 19-38, 38-57, and 38-57 indicate poor, moderate, and very good job satisfaction, respectively. This questionnaire has been used in many types of research in the world [21-26]. Its internal consistency reliability was measured $\alpha = 0.87$.

Diener et al.'s Satisfaction with Life Scale (SWLS) is a 5-item instrument designed to measure a person's cognitive and overall judgment of life. This instrument is scored based on a 7-point Likert scale ranging from 1 (Completely disagree) to 7 (Completely agree). The overall score of this scale is calculated by summing the answers and the possible score range is 5 and 35. A higher score indicates higher levels of life satisfaction. This questionnaire has also been used in many types of research in the world [27-32]. The Cronbach's α reliability was 0.86.

Derogatis et al.'s Symptom Checklist-90 (SCL-9) can be completed within approximately 25 minutes. This questionnaire is the short form of SCL-90 and was extracted by Najarian & Davoudi based on the original form and through exploratory factor analysis. It consists of 25 items and 9 subscales of somatization (6 questions), obsession-compulsion (3 questions), interpersonal sensitivity (3 questions), depression (2 questions), anxiety (3 questions), phobia (3 questions), paranoid thoughts (1 question), psychosis (3 questions), hostility (1 question). SCL was answered according to its original form and based on a 5-point Likert swale ranging from None or Rarely (0), A little (1), To some extent (2), A lot (3), Very much or Strongly (4). The overall score of general psychological injuries was extracted. Higher scores indicate more damage [30]. The Cronbach's alpha reliability of the tool was calculated α = 0.94.

The collected data was analyzed using descriptive tests (frequency, mean percentage, and standard deviation) and non-parametric Spearman and Kruskal-Walli's correlation tests in SPSS ver. 22. P-value<0.05 was considered as the significance level in all tests.

Ethical considerations: The present study was approved by the Ethics Committee of Ilam University of Medical Sciences with the code IR.MEDILAM.REC.1400.229. The contents of the Nuremberg and Helsinki declarations and the 26 research ethics codes were observed.

RESULTS

The results showed that most of the participants were female (61.2%), aged 26-29 (40%), single (52.5%), childless (75%), owning their own house (72.5%), and had 6-10 million-toman income (70%). Also, the majority of participants had a bachelor's degree (88.8%), less than 6 years of work experience (70%), were ward nurses (91.2%), were permanent nurses (45%), and worked in ICUs (45%).

Table 1 shows the correlation matrix of job satisfaction, life satisfaction, and mental health. This table determines the relationship between job satisfaction, life satisfaction, and mental health of research subjects. The table shows no significant relationship between the total score of mental health and the total score of job satisfaction. There was a significant relationship between the total job satisfaction score and life satisfaction score (r=0.267, p=0.001). There was also an inverse and significant relationship between the total mental health score and the life satisfaction score (r=0.294, p=0.001).

Kruskal-Walli's test shows the relationship between job satisfaction, life satisfaction, and mental health according to demographic characteristics (Table 2). This table shows that the highest frequency of the variables of work experience, education level, medical training center, hospital ward, income level, and employment status are related to less than 3 years (p=0.017, df=4, k=11.98), BA (p=0.014, df=1, k=6.07), Ayat-Allah-Taleghani hospital (P=0.004, df=2, k=11.03), ICUs (P=0.001, df=2, k=55.91), 6-10 million tomans(P=0.022, df=2, k=7.62), and contractual employment (P=0.001, df=2, k=14.37), which are all had a statistically significant relationship with job satisfaction. The highest frequency of gender, marital status, and employment status were related to females (P=0.037, df=1, k=4.34), married individuals (P=0.034, df=1, k=4.47), and contractual individuals (p=0.032, df=2, k=6.88), which all had a statistically significant relationship with life satisfaction. Also, the female gender (k=11.75, p=0.001, df=1) had a statistically significant relationship with mental health.

DISCUSSION

Mental health affects health-related variables related to [4,33-35]. The results of the present research showed no significant relationship between each of the mental health components and the total score of job satisfaction. There was also no significant relationship between the total scores of job satisfaction and mental health. However, there was an inverse and significant relationship between the two components of job satisfaction and some mental health components, that is between the payment system with physical complaints, interpersonal sensitivity, phobia, and the overall mental health score, and also between the type of job with obsessive-compulsive and paranoid thought.

Kahe et al. revealed a statistically significant relationship between overall job satisfaction with employees' mental health, and people with high job satisfaction obtained a better mental health score (below average) (p=0.02). In other words, the lower the level of mental health, the lower the job satisfaction and vice versa [36].

Table 1: Correlation matrix of job satisfaction, life satisfaction, and mental health (Spearman correlation)

Variable			*Correlation*

Veysey et al. showed an inverse relationship between the general health questionnaire and job satisfaction and a direct relationship with the increase in cases of stress [37]. In her study in teaching hospitals of Hormozgan, Mastaneh et al. (2013) also showed a significant negative correlation between mental health pay satisfaction ($p<0.005$) and type of work ($P<0.01$) [38].

Sarafis et al. also showed a significant relationship between the stress management domain of health-promoting lifestyle and the payment system domain of job satisfaction ($p< 0.005$) [39].

Ghasemipirbalooti et al. found a statistically significant relationship between mental health and job satisfaction of the employees of Shahrekord University of Medical Sciences ($p=0.001$) [40].

Mei et al. (2015) investigated the effect of psychological characteristics of employees on their performance and job satisfaction and the indirect effect of feelings on their relationships. They concluded a positive and direct relationship between job satisfaction with psychological characteristics and positive feelings of employees [41].

Many studies have shown a direct relationship between mental health and job satisfaction [42-47].

The results of this study show an inverse and significant relationship between life satisfaction and each of the components of mental health except for the "paranoid thought" component. The results also show that the level of mental health of nurses increases and mental injuries decrease with increasing life satisfaction scores. Salimi also showed in research titled "Investigating mental health and its relationship with job burnout and life satisfaction of employees" that there is a significant relationship between mental health and life satisfaction.

The consistency between the results of the present research with Salimi's study is attributed to the correlation between mental health and life satisfaction. That is, life satisfaction prerequisite for mental health, and if there is no satisfaction, negative mood and despair dominate the person and make him/her susceptible to all kinds of mental illnesses [48].

In a study on nurses in Ahvaz government hospitals, it was found that life satisfaction is correlated with high mental health (Birgani et al.). The higher the level of life satisfaction, the more likely a person is to experience positive emotions and feelings [49]. Geravand also showed in a study that mental health has a direct effect on life satisfaction.

Changes in mental health and emotions can lead to changes in life satisfaction and a person's attitude [50]. The results of various research show a significant relationship between mental health and life satisfaction. The results of Ferguson's study indicated the interaction between mental health and life satisfaction [51].

In a study of the level of job satisfaction of nurses in hospitals affiliated with Kashan University of Medical Sciences and related factors, Tagharobi et al. showed a statistically significant relationship between the level of education, major stress in the last six months, the workplace, the level of life satisfaction, mental health satisfaction health, pay satisfaction, satisfaction with the number of employees in each shift, satisfaction with the feedback of patients and their families, satisfaction with the treatment and performance of doctors, satisfaction with the treatment and performance of head nurses and colleagues, satisfaction with the treatment and performance of nursing office managers, satisfaction with workplace amenities and happiness with job satisfaction [52].

As was pointed out by Grant, nurses are among the most vulnerable working group in society, and their health and personal-family life balance are strongly related to occupational variables. Work and family life conflict and subsequent stress cause psychological symptoms such as higher stress, depression, chronic physical problems, increased physical complaints, lower life satisfaction, low quality of family life, and low energy levels in these people [17].

CONCLUSION

According to the results of the present study, nurses' life satisfaction score increases with the increase in their job satisfaction score. But there is no significant relationship between the total mental health score and the total job satisfaction score. However, there is an inverse and significant relationship between mental health and life satisfaction. On the other hand, the level of mental health of nurses increases, and mental injuries decrease with the increase in life satisfaction scores. Considering the vital role of nurses in achieving the goals of the health system and public health, neglecting the job dissatisfaction of nurses may have consequences such as reducing productivity, reducing the level of responsibility, reducing the level of quality of their performance, reducing life satisfaction and increasing the number of psychological injuries. Job satisfaction is effective in creating motivation, efficiency, responsibility, and social accountability in the personnel of any organization. Job dissatisfaction can lead to complications such as job burnout, illness, absenteeism, the job left, leaving many nursing jobs, and the reluctance of the young workforce to attend the wards. Therefore, it is necessary to make further efforts in this field by healthcare policymakers.

Abstract: *Introduction: Self-care behaviors are very important to control type 2 diabetes. The current study was conducted aiming at determining the effect of the educational intervention based on mobile short message service on the self-care behaviors in patients with type 2 diabetes in Khorram Abad. Methods: This study was a semi-experimental study on 191 patients with type 2 diabetes (45case and 45 controls). Data collection tools included a demographic information form, International Physical Activity Questionnaire, Self-Care Scale, and Self-Efficacy Scale. Three to four educational messages were sent daily through mobile phones as an educational intervention. Data were analyzed with SPSS V24 at a significance level of 0.05. Findings: The data analysis indicated that the average score of self-care, self-efficacy, and blood sugar was significantly higher in the case group than in the control group before and after the intervention (P<0.001). However, in terms of the physical activity variable, this relationship was not statistically significant in the case and control groups. Conclusion: Educational interventions to empower diabetic patients by strengthening their self-care can be an effective way to improve the health of diabetic patients. Therefore, it is suggested to use patient empowerment programs, especially with a self-care approach, to improve the health of patients.*

Keywords: *self-care, self-efficacy, physical activity, blood sugar, type 2 diabetes*

INTRODUCTION

Diabetes is the most common disease caused by metabolic disorders, which is mainly characterized by a chronic increase in blood sugar and disturbed carbohydrate, fat, and protein metabolism. In general, diabetes is a multifactorial disorder diagnosed by a chronic increase in blood sugar or hyperglycemia (according to diagnostic criteria) and is caused by a disorder in insulin secretion or function or both [1]. Retinal damage and blindness, peripheral neuropathy, leg pain, stroke, peripheral vascular problems, end-stage renal disease, and limb amputation are among the most serious complications of diabetes [2]. The most common type of diabetes is type 2 diabetes, which accounts for approximately 90-95% of diabetes cases and is usually associated with metabolic disorders, weight gain, and physical inactivity [3]. About 422 million people worldwide suffer from diabetes, the majority of whom live in low- and middle-income countries, and in 2019, diabetes was introduced as the direct cause of 1.5 million deaths [4]. According to the International Diabetes Federation (IDF), the number of diabetic patients will reach 439 million people in 2030, and the prevalence of diabetes in developing countries will be 69% [5]. More than 3 million people with diabetes live in Iran [6]. By 2030, Iran will be one of the most prevalent regions in the world in terms of diabetes [7]. Paying attention to the chronic and costly nature of this disease for the general health of society and the creation of a large financial burden, it is essential to pay serious attention to this problem and its consequences [8]. According to the results obtained from the studies, the long-term complications of this disease, including neuropathy, nephropathy, and retinopathy can be prevented, or at least the occurrence of these complications can be postponed if blood sugar is controlled [9, 10]. Many studies have found physical activity and exercise to be effective in reducing blood sugar levels and controlling diabetes [11,12]. The World Health Organization considers education to be the basis of diabetes treatment. Therefore, self-care is one of the important topics of diabetes treatment. Self-care is a learned regulation function in humans, which is based on the ability of people to perform care actions on themselves [13]. It includes the behaviors of following a proper diet, taking medicine on time, self-monitoring of blood sugar, performing regular physical activity, and physical care of the feet [14]. Studies show that 67% of patients with type 2 diabetes do not monitor their blood sugar according to the recommendations. Also, only 19-30% of diabetic patients use the recommended physical activities and compliance with nutritional behaviors in these patients is 65%, and only 7% of diabetic patients fully adhere to all aspects of self-care behaviors [15, 16]. Self-efficacy is also known as a strategy to improve self-care in diabetic patients, which results in self-confidence and adherence to care recommendations to control blood sugar in these patients [17].

Nowadays, to follow up and educate diabetic people, new communication systems are required to direct the focus of care and treatment from the clinic to the patient's daily life. Researchers have pointed out the use of mobile phone service as a method of education and follow-up in chronic diseases, that short message is one of the main functions of mobile phone in the education of diabetic patients [18,19].

Considering the importance of self-care in controlling the blood sugar of diabetic patients and the value of self-efficacy as one of the self-care approaches, it seems necessary to design educational interventions on the platform of mobile phones and in the form of short messages as a relatively new educational method in controlling the disease of diabetics. Thus, the present study was conducted to determine the effect of the educational intervention based on mobile phone short messages on self-care in patients with type 2 diabetes referred to the diabetes clinic in Khorramabad.

MATERIALS AND METHODS

The present study was a semi-experimental intervention research with a pre-test and post-test design. The sample size was specified as 90 people who were selected from the research population of patients with type 2 diabetes referring to the diabetes clinic in Khorramabad, Lorestan province. The participants were selected according to the inclusion criteria using random sampling. Then, they were divided into case and control groups using a simple randomization method (45 ones in each group). The inclusion criteria include informed consent to participate in the research, having a minimum level of literacy and understanding of the content sent through text messages, having a fixed personal mobile number to receive educational SMS, lack of any serious diabetic complication, and not having special diets because of specific diseases or physical problems limiting physical activity. Exclusion criteria include suffering from serious complications of diabetes during the study, suffering from diseases that limit physical activity or nutrition, and the patient's unwillingness to receive educational messages.

Data collection tools in this study included a demographic information form, International Physical Activity Questionnaire (IPAQ), a Self-Care Scale developed by Tubert, and Self-Efficacy Scale. Demographic information included: age, height, weight, gender, educational level, employment status, marital status, and type of treatment. The IPAQ with seven items measured the duration of physical activity in the last week in four categories: moderate physical activity, intense physical activity, walking, and sitting activities. According to the scoring protocol in this questionnaire, the intensity of physical activity based on the ratio of energy consumption in terms of metabolic equivalent of task (MET) in the last seven days is classified into three levels: low, medium, and high. It was proposed by the World Health Organization and the Centers for Disease Control and Prevention in 1998 to measure the physical activity of people aged 15 to 69 years and its validity and reliability have been confirmed in 12 countries worldwide, including Iran [20,21]. A self-care questionnaire was used in this study that included 15 items in the areas of diet compliance, physical activity, blood sugar monitoring, insulin injection or diabetes pill consumption, foot care, and smoking, which was translated and standardized by Hamdzadeh [22,23]. The self-efficacy questionnaire, which is one of the constructs of the standard Health Belief Model Questionnaire, validity and reliability of which have been confirmed [24].

After presenting a letter of introduction from the Iran University of Medical Sciences and obtaining the necessary permits, the researcher referred to a diabetes clinic in Khorram Abad and selected 90 people from among 200 eligible people using random sampling. People who were willing to participate in the study and met the inclusion criteria were assigned to the case and control groups (45 in each group) using a simple randomization method. After random allocation, blood sugar samples were taken in all groups four days before the start of the intervention. In the first session, the researcher explained the purpose of the meeting to the participants, and written informed consent was obtained. Then, the personal information form and questionnaires were completed by the case and control groups. The case group received an educational program in the form of short educational messages via mobile phone, for four weeks and on average, at least three to four messages per day related to the educational content, including exercise, self-monitoring of blood sugar, diet, insulin therapy, medication use, and foot care. For example, short messages about physical activity and blood sugar monitoring were “for people with diabetes, walking is the best exercise” or “it is better for people with diabetes to measure their fasting blood sugar after waking up”. To improve self-efficacy, encouraging messages about adherence to self-care were used.

Finally, after two months, the same questionnaires (demographic, physical activity, self-care, and self-efficacy scales) were distributed and completed by the participants, and the blood sugar levels of the two groups were measured again. During this period, the control group did not receive any educational intervention.

However, to comply with the ethical principles, an educational CD containing self-care training was given to the control group after completing the research. The data of the two groups before and after the intervention were entered into SPSS version 24 software and analyzed using Wilcoxon, Mann-Whitney, Chi-square test, independent t-test, and paired t-test at a significant level of 0.05.

RESULTS

The participants’ average age was 51.01 ± 0.967, and the average height and weight were 164.57 ± 1.031 and 75.69 ± 1.101, respectively.

Before the implementation of the educational program, the case and control groups were matched in terms of demographic variables, including age, height, weight, gender, education, employment status, marital status, and type of treatment, and no statistically significant difference was observed between the two groups (Table 1).

Table 1: Comparison of the absolute and relative frequency distribution of demographic variables in case and control groups

Variable		Case		Control		P value
		No.	%	No.	%	
Gender	Female	31	69	26	57/7	0.796
	Male	14	31	19	42/2	
Employment	Unemployed	5	11	2	4	0.686
	Housewife	26	58	24	53	
	Self-employed	9	20	9	20	
	Public	5	11	10	22	
Education	Illiterate	5	11	4	9	0.479
	Primary school	17	38	10	22	
	Secondary school	9	20	5	11	
	High school	4	9	11	24	
	High school diploma	4	9	10	22	
	Higher education	6	9	5	11	
Marital status	Single	2	4	1	2	0.800
	Divorced	1	2	0	0	
	Widow	9	20	5	11	
	Married	33	73	39	87	
Type of treatment	Insulin	21	47	21	47	0.920
	Oral medication	20	45	22	49	
	Diet	4	9	2	4	
	Exercise	0	0	0	0	

As observed in Table 2, there is no statistically significant difference in terms of the average score of physical activity, self-care, self-efficacy, and blood sugar between the case and control groups before the intervention, while after the intervention, the average scores of these variables, except for physical activity (P=0.8), was significantly higher in the case group compared to the control group (P<0.001). In the control group, before and after the intervention, no significant difference was observed in the average scores of physical activity, self-care, self-efficacy, and blood sugar (P>0.05).

Table 2: Comparison of the average scores of physical activity, self-care, self-efficacy, and blood sugar, before and after the intervention in case and control groups

Scale	Group	Case	Control	p-value
		Mean ± SD	Mean ± SD	
Physical activity	Before intervention	677.5±954.938	307.5±461.75	0.6
	After intervention	903.75±973.125	655±925.625	0.8
	p-value	0.8	0.4	_
Self-care	Before intervention	2.31±0.813	2.38±0.844	0.12
	After intervention	3.38±0.688	2±0.906	0<0001
	p-value	0<001	0.22	_
Self-efficacy	Before intervention	2.7±0.4	2.7±0.3	0.15
	After intervention	3.7±0.7	2.7±0.7	0<0001
	p-value	0<001	0.286	_
Blood sugar	Before intervention	180±80.5	185±51	0.8
	After intervention	170±87.5	180±70.5	0<001
	p-value	0.009	0.491	_

Table 3: Comparison of blood sugar scores before and after the educational intervention in the case group

Method of treatment	Blood sugar level before the intervention	Blood sugar level after the intervention	Level of change
Insulin	227.09	217.92	-9.17
Oral medicine	173.48	170.65	-2.83
Diet	181	180.44	-0.56
Exercise	194	194.5	0.5
Medium	193.89	190.88	-3.02

Table 3 indicates that the blood sugar level in all patients with different treatment methods (insulin, oral medication, diet) in the case group reduced after the educational intervention compared to before intervention, except for the patients who only used exercise to control their blood sugar.

DISCUSSION

The present study was conducted aiming to determine the effect of the educational intervention based on mobile phone short messages on self-care in patients with type 2 diabetes referred to the diabetes clinic in Khorramabad. The research findings suggest that the educational intervention through mobile phone short messages improved self-care in the case group, which is consistent with findings by Abaza et al. [25] and Agbede et al. [26] on the effect of the intervention based on mobile phone short messages in the self-care of diabetic patients and the findings by Yari et al. [27] and Rahnavard et al. [28] concerning SMS-based and self-care education of diabetic patients. Krishna et al. [29] reported that technologies such as mobile phones and text messages, which are currently part of people's daily lives, have the potential to influence self-care and improve people's health. The approach of health education through SMS to promote self-care in diabetic patients is more welcomed than traditional approaches that require reading pamphlets or attending lectures [25,30].

In this study, self-efficacy also there was a significant difference in the case group in terms of self-efficacy after the educational intervention. Katz and Nordwall [31] and Peymani et al. [32] also found that interventions based on mobile phone messages improve self-efficacy and self-care. Similar studies [33,34] regarding the self-care of diabetic patients also indicate a significant difference in the average score of self-efficacy and self-care in the case group compared to the control group after the educational intervention. These studies are consistent with our work in that increasing self-efficacy causes the adoption of self-care behaviors in diabetic patients. Self-efficacy is an important prerequisite for behavior change [35]. An individual with low self-efficacy is less likely to make an effort to perform a new health behavior or to change the behavior he is used to [36]. Researchers believe that self-efficacy has a suitable framework for understanding and predicting and patient's commitment to self-care behavior in the treatment of diabetes [37].

The results of the present study showed that education through mobile phone short messages does not affect increasing physical activity in the case group, which is in line with the findings by Bakhshian et al[38] regarding the effect of education through mobile phone short messages on self-care of patients with type 2 diabetes. It is also in agreement with the findings by Kim et al. [39] on adherence to diabetes control recommendations, while our findings are not consistent with the study of Paul et al. [40] regarding the use of software that can be installed on mobile phones to improve the amount of daily walking in patients with a history of stroke and the study Martha et al.[41] concerning mobile phone SMS intervention on diabetes self-care activities, cardiovascular disease risk awareness, and food choices among type 2 diabetic patients. This discrepancy can be due to the lack of sports facilities and parks in the current study or the addition of chronic diseases to the patients participating in this research, as well as social and cultural factors that prevent people from doing physical activities in public environments. In the present study, since the number of women is more than men, the problem of social and cultural factors could be more marked.

The use of mobile phone messages in the current study showed a significant positive effect on the reduction of blood sugar in the case group after the educational intervention, which is consistent with the findings of similar studies in this field [42,43,44]. In patients suffering from diabetes, education is as valuable as medicine, exercise, and diet, because the treatment will never be effective unless the patient is well aware of the nature of his disease and takes positive steps to deal with it.

CONCLUSION

The results of this study demonstrated that educational interventions based on mobile phone short messages can be effective in enhancing self-care in patients with diabetes. Educational interventions aimed at empowering diabetic patients by strengthening self-care in them can be an effective way to improve the health of patients with diabetes. Therefore, it is recommended to use patient empowerment programs, especially with a self-care approach, to improve the health of patients.

Conflicts of interest and sources of funding

The personal interests of the authors were not related to the results of this research.

The authors declare that they have no competing interests. This study did not receive any grant from funding agencies.

Abstract: *Trust in health care professionals is considered as a basis for patients' care. This study aimed to compare the level of patients' trust in physicians and nurses in both general and COVID-19 wards in a reference hospital in Tehran during the pandemic. This was a cross-sectional descriptive study. The study population comprised patients from Baqiyatallah Hospital in 2022. The data collection tool was the scale of patients' trust in nurses and the Wake-Forest physician trust scale. Data analysis was performed using SPSS-26 software. The level of patients' trust in physicians in COVID-19 wards was significantly lower than in Non-COVID-19 wards (P<0.001), but there was no difference between the two groups in the trust of nurses. The lowest level of trust was in the receiving of required information from nurses, which had a lower score compared to other questions in the questionnaire, and the average amount of receiving required information for patients in general wards was significantly lower than that of patients in COVID-19 (P=0.006). Trust in nurses and physicians in both COVID-19 and general wards was optimum. During the COVID-19 pandemic, the medical staff worked tirelessly and despite the difficulties and complications of the pandemic, patients have high trust in physicians and nurses.*

Keywords: *trust; nurses, physicians; COVID-19; coronavirus*

INTRODUCTION

Physicians and nurses, as the main members of the medical staff, take on different roles, considering the physical, psychological, and social needs of patients. They may act as educators, counselors, mentors, informers, advocates, and act as experts. To play such roles, physicians and nurses need to establish a good relationship with their patients [1,2]. Trust forms the basis of the relationship between the physician or nurse [3] and patient and provides the conditions for the physician or nurse and patient to work together for a better care plan [4]. The relationship between trust and health outcomes is different in individual studies [5]. For example, in a sample of patients with diabetes, trust in a healthcare professional was positively associated with objective and mental health outcomes (glycemic control, health-related quality of life, and patient satisfaction] [6].

The hypothetical relationship between trust and health outcomes is also reinforced by the ethical claims derived from trustworthy and patient-centered relationships in clinical settings [7]. Studies show that patients who have more trust in their therapist are more satisfied with the care and are more likely to follow treatment recommendations [8,9]. Patients' experiences of trust in nursing depend on nurses' knowledge, and the commitment to conversation to build and develop relationships [10]. Therapeutic staff must receive appropriate training to build a bond of trust between themselves and the patient to establish a trustable relationship between themselves and the patient [11]. Trust between patient and therapist is essential to reduce patients' anxiety and build the capacity to control them [12]. The COVID-19 epidemic has created special conditions in the relationship between the medical staff and patients [13]; furthermore, the need for social distancing and the use of protective equipment on the one hand, as well as an increasing number of patients, especially those with severe illnesses, epidemics, illnesses and dementia and lack of time to provide medical care, on the other hand, has created a different kind of doctor-nurse relationship with the patient that may affect patients' trust [14]. Considering the importance of patients 'trust in physicians and nurses in adhering to treatment and the effectiveness of medical care, this study was designed to compare the level of patients' trust in physicians and nurses in general and COVID-19 wards in a reference hospital in Tehran during the pandemic.

MATERIALS AND METHODS

This study was descriptive and cross-sectional. The study population consisted of patients admitted to both the general and COVID-19 wards of Baqiyatallah Hospital, Tehran, Iran in 2022. Inclusion criteria included the age range of age: 20-70, hospitalization for more than three days in hospital wards, having no serious psychological disorders, and submitting consent to participate in the study. The data collection tools included the patient's trust scale in the nurse and the Wake-Forest physician trust scale. The Nurse Trust Scale has been validated by Nouripour et al [15]. The Physician Trust Questionnaire has been validated by Forati et al [16].

The scale of patient trust in the nurse contains five questions about Responding to the need, Usefulness of measures, Trust in measures and Practice of treatment" and Giving sufficient information to the patient by the nurse with the scales Never, Rarely, Sometimes, Most of the time, Usually, Always". The Physician Trust Questionnaire includes nine questions about Trust in Skills, Treatment Selection, and Physician Decisions on a scale of "Strongly Agree, Agree, Neither Agree Nor Disagree, Strongly Disagree and Disagree".

Patients with more than three days of hospitalization were randomly selected from the ward list. First, patient satisfaction with the study was obtained and then a questionnaire about patients' trust in physicians and nurses was filled in by an interviewer. Data analysis was performed using SPSS-26 software. Descriptive analysis was performed with mean, standard deviation, frequency, percentage, and analytical analysis depending on the type of data with t-test and Chi-square test.

RESULTS

Four hundred patients participated in this study. Descriptive values related to the age of these patients by group and in general are displayed in Table 1. The mean age of patients in the COVID-19 group was 53.3 years and in the Non-COVID-19 group was 53.8 years. This study included 257 male patients (64.3%). In addition, the sex distribution was the same in the two groups of patients with COVID-19 and Non-COVID-19 and no significant difference was observed in the sex distribution of the two groups (P=0.132).

Table 1: Descriptive characteristics of the patients admitted to Covid-19 and non-Covid-19 wards

Variable		COVID-19	Non-COVID-19	P Value
Age (Mean ±SD]		5.3 ± 14.53	3.8 ± 17.53	0.11
Sex	Male	120	137	13.0
	Female	79	65	
Education	Less than a Bachelor's degree	99 (54.1 %)	147 (8.72 %)	<0.001
	Bachelor degree	57 (1.31 %)	49 (3.24 %)	
	Senior	22 (0.12 %)	5 (5.2 %)	
	PhD	5 (7.2 %)	1 (5.0 %)	

In total, 198 patients (49.5%) with COVID-19 and 202 (50.5%) Non-COVID-19 patients were considered in this study. The overall mean of trust in nurses in the COVID-19 group was not significantly different from that of the Non-COVID-19 group.

Most people in both COVID-19 (85.3%) and Non-COVID-19 (86.6%) groups reported that nurses were available, most of the time or always when they needed them.

Most patients in both COVID-19 (99.4%) and Non-COVID-19 (97.4%) groups believed that the nurse's activity was useful to them, most of the time or always. The mean usefulness of therapeutic activities in patients in general wards was 0.1 higher than in patients in COVID-19 wards but this difference was not significant (P>0.05).

Most patients in both COVID-19 (99%) and Non-COVID-19 (95%) groups believed that they trusted the care of nurses always. The average level of trust in medical care for patients in general wards was 0.1% lower than that of patients in COVID-19 wards. But the difference was not significant (P>0.05).

In the COVID-19 group, 93% of patients often or always followed the advice of the nurses, while in the Non-COVID-19 group, 96.5% of patients most of the time or always followed the statements and recommendations of the nurses. The mean rate of treatment of patients with therapeutic recommendations in general wards was significantly higher (0.4) than patients admitted to the COVID-19 ward (P<0.001).

In the COVID-19 group, most patients (71.8%) believed that most of the time, or always, nurses provided enough accurate information about their disease. While in the Non-COVID-19 group, about half of the patients (55%) believed that most of the time or always the nurses provided them with sufficient accurate information about their disease. The average amount of information required for patients in general wards was 0.3 less than for patients admitted to the COVID-19 ward. There was a significant difference in the amount of information required for patients in general wards and COVID-19.

Table 2: Descriptive values related to the trust variables of the patients admitted in the Covid-19 and non-covid-19 wards

Variable	COVID-19			Non-COVID-19		
	SD ± Min	Min	Max	SD ± Min	Min	Max
Responsibility for patient needs	4.6 ± 1.1	2	6	4.6 ± 1.1	2	6
The usefulness of therapeutic activities	8.2 ± 0.5	3	6	8.3 ± 0.5	1	6
Reliability of medical care	3.5 ± 8.0	3	6	2.5 ± 1.1	1	6
Following the recommendations	5±0.9	3	6	4.5±0.9	2	6
Patients' access to the necessary information	4.2± 1.3	1	6	3.9± 1.6	1	6
Satisfaction with the nurse	7.0 ± 9.4	2.6	6	7.0 ± 9.4	2.6	6
Satisfaction with the physicians	3.5±0.3	2.8	4.3	3.7±0.3	2.2	4.5

DISCUSSION

Patients’ trust in nurses and physicians is important and at the same time complex phenomenon that to achieve it, some professional characteristics must be created and strengthened and some ethical principles must be observed [17]. In the study of patients' trust in nurses of Baqiyatallah Hospital, Tehran, Iran, we used the questionnaire of patients’ trust (P=0.006). The results of the study assessing the patients’ trust in the physicians showed that most patients participating in the study in both groups of COVID-19 (92.4%) and Non-COVID-19 (97.5%) had a high level of trust in physicians. Considering the mean difference, it can be said that the average trust in physicians in COVID-19 patients was significantly lower by 0.14 than in Non-COVID-19 patients (P<0.001).

Ravdin and Cabral nurses, which was validated by Nouripour et al [15]. This questionnaire had five questions, and in what follows, we will review the results obtained from the questions.

The level of responding to patients' needs and being available to them when needed, the level of use of treatment activities, and the level of trust in medical care in both general and COVID-19 wards were desirable. The rate of follow-up to treatment recommendations was favorable in both groups, but the mean rate of follow-up to treatment recommendations of patients in general wards was significantly higher than patients admitted to the COVID-19 ward. Studies have shown that there is a positive relationship between the level of trust in the nurses and the level of treatment adherence [18]. Trust in the health care specialist has been proposed as a basis for effective and basic treatments for patient-centered care [19-21]. However, the novelty of COVID-19 and the fact that there is still no definitive cure for the disease is a problem noted in the study by Baker [22]. The lack of definitive treatment and protocol for this disease and frequent changes in health protocols during this period may reflect scientific uncertainty; meanwhile, the uncertainty of scientific evidence reduces patients' trust to follow the recommendations of medical staff compared to other diseases and overshadows their treatment adherence.

In this study, the lowest level of trust was in the average amount of information required for patients, which had a lower score compared to other questions in the questionnaire, and the average amount of information required for patients in general wards was 0.3 less than patients in the COVID-19 ward. Nurses in both the COVID and general wards have the lowest level of patients’ trust in providing the necessary information. In Ozaras and Abaan study, the use of medical terms or terms that the patient does not fully understand, the lack of anticipation or understanding of patients' information needs, and neglecting responsibilities and factors related to nursing work such as busyness, etc. have been mentioned as important causes in reducing the provision of the necessary information to patients [23]. It seems that to improve the provision of information to patients, some programs should be implemented in the hospital and the nursing department.

The level of patients' trust in physicians in COVID-19 wards was significantly lower than in Non-COVID-19 patients. Gupta et al. showed that the pandemic coronavirus disease 2019 (COVID-19) has posed new threats to the trust in medical staff [24]. Factors such as the high prevalence and involvement of doctors during the epidemic peaks, as well as the specific way of communicating with the patient (personal protective equipment and social distancing, etc.] and that the patient does not even know and see the face of the treating physician well, are involved in this issue [25]. Identifying the causes of this difference requires further study and investigation of the issue from different respective.

CONCLUSION

Trust in nurses and physicians in both COVID-19 and general wards was optimum. This finding indicates that during the COVID-19 pandemic, the medical staff worked tirelessly and despite the difficulties and complications of the pandemic, patients have high trust in physicians and nurses.

Abstract: *How people behave in an emergency depends on many social, cultural, and contextual factors. This study aimed to determine the COVID-19 risk perception in Iranian people. This study was descriptive. The study population was the assistant of patients who had come to Baqiyatallah Hospital in 2021. The number of participants was 500. The study tool was the COVID-19 risk assessment questionnaire. Data were analyzed using SPSS-22 software. The mean risk perception score was 2.78(±0.6) on a 7-point scale. The lowest and highest mean of the predictors of risk perception in COVID-19 was trust in government and personal efficacy, respectively. There was a significant difference between men and women in the mean of collective efficacy (P= 0.032). Social knowledge (p=0.007), trust in science (p=0.001), and trust in medical professionals (p=0.050) in positive direct experience people were significantly more than in people with negative direct experience of COVID-19. The most important predictors of risk perception in the COVID-19 epidemic were gender, education, social knowledge, and trust in science (P<0.05). People's perception of the risk of COVID-19 depends on several various factors, the most important factors were gender, level of education, social knowledge, and people's trust in science.*

Keywords: *COVID-19; coronavirus; risk perception*

INTRODUCTION

The coronavirus disease 2019 (COVID-19) is caused by the severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) and has spread around the world quickly, emerging as a significant challenge of the current century for public health, the economy, markets, and policies in many countries [1].

The coronavirus outbreak was declared a public health emergency of international concern by the World Health Organization on 30 January 2020. Today, most people around the world have understood the outcomes of COVID-19 infection and they have accepted the need for hand hygiene and social distancing to prevent its spread. But, some of them ignore or delay hygienic actions, government laws, and social distances in public places, or homes. The fact that individuals in the same situation of common challenge act so differently indicates that the persons' risk perception relating to this new and chronic challenge is strongly different [2].

How people behave in an emergency depends on their understanding of the severity and depth of the risk and the extent of their vulnerability, but many social, cultural, and contextual factors may influence their risk perception [3]. Little is known about how people perceive the risk associated with emerging infectious diseases compared to other areas of risk. Risk perception leads to the adoption of preventative health behaviors so misperception of COVID-19 risk in this condition can lead to negative consequences of pandemic control [4].

Personal experience with the virus, individualistic and prosocial values, hearing about the virus from friends and family, trust in government, science, and medical professionals, personal knowledge of government strategy, and personal and collective efficacy were all significant predictors of risk perception, in the first global assessment of public risk perception of COVID-19 [5].

Previous studies have examined differences in risk perception of COVID-19 in diverse populations and races. Health workers reported higher risk perception, level of worry, and knowledge as related to COVID-19 infection compared to the general population [6]. In some studies, females were found to perceive risks higher, complied more with the government's guidelines, and coped better than males in response to COVID-19 [7]. But Self-reported anxiety over the pandemic is a crucial predictor in explaining risk perceptions in all age and gender groups [8]. And overall public initial concerns and trust can play an essential role in improving the perceived risk of a pandemic and increasing public participation in adopting preventive measures [9]. This study aimed to determine the risk perception score and its related factor in Iranian people.

MATERIALS AND METHODS

This study was descriptive-analytical. The study population was the assistant of patients who had come to the clinic of Baqiyatallah Hospital in 2021. The inclusion criteria were 15 to 80 years old, no serious and acute illness, and consent to participate in the study. The number of participants in the study was 500, with a 5% alpha error and 20% beta error. The study tool was the COVID-19 risk assessment questionnaire, which was designed by Dryhurst [10] using previous studies to identify all dimensions of risk perception covering affective, cognitive, and temporal-spatial dimensions to provide a holistic measure of risk perception. The questionnaire included items on COVID-19 experience, demographic variables (age, gender, and education) knowledge, both personal and social knowledge, social amplification, prosociality, individualism, trust in l three domain of science, medical professionals, and government, personal efficacy, and collective efficacy. The validity of the COVID-19 risk assessment questionnaire was assessed using face and content validity approaches. The impact score of each item was assessed to evaluate the face validity. The questionnaire was distributed among 10 technical experts who were asked to evaluate items based on the mentioned criterion. Then the importance of each item was calculated using the impact score formula and the results were compared with the standard score (1.5), and items whose scores were higher than the standard score were included in the questionnaire. Next, the content validity of the instrument was analyzed using the Content Validity Ratio (CVR) and Content Validity Index (CVI). 10 respondent experts also participated in this phase. Experts were asked to group items as "essential", "essential but not useful", or "not essential" to calculate CVR. Their responses were calculated based on the CVR formula and the results were compared with Lawshe's Table. Numbers higher than 0.6 were approved. CVI survey was done based on the Waltz and Basel content validity index [11]. A questionnaire was distributed among the experts who were asked to rank 24 items based on a four-part Likert scale as compatible with 3 criteria of relevancy, simplicity, and clarity. (For example, unrelated items, partially related items, related items, and fully related items were scored 1, 2, 3, and 4, respectively). Items higher than 0.6 were approved according to the CVI score. Cronbach's alpha method was used to assess the questionnaire's reliability. Data collection was started after the standardization of the questionnaire.

Patients completed the study questionnaire, after written consent. The questionnaire was filled out using the interview method and by a trained interviewer. All information obtained from patients was confidential and the study received an ethics code from the ethics committee of Baqiyatallah Hospital. Primary data were analyzed using SPSS-22 software. Descriptive data analysis was performed using mean and standard deviation in quantitative data and frequency and percentage in qualitative data. Analytical analysis was performed according to the normality of the data with parametric and non-parametric tests. Linear and logistic regression were used to measure the relationship between variables according to the type of data.

RESULTS

The validity and reliability of the instrument of this study

In the first step, the COVID-19 risk assessment questionnaire was validated. Tables 1 and 2 show that the scores of all items of the questionnaire were higher than the criterion score (i.e. 1.5) and experts approved the quantitative face validity of all items. Moreover, the results of CVI indicate that all items of the questionnaire obtained a score higher than 0.6, and content validity was considered appropriate by experts. The reliability of the questionnaire based on Cronbach's alpha was 0.79, 0.69, and 0.77 for risk perception, individualism, and trust in science, respectively.

Study findings

In the study samples, 500 people participated, of whom 253 (50.6%) were women and 247 (49.4%) were men.

The mean age of participants was 38.9 (±11.7) and 147 (29.4%) of the people have experienced the disease. The descriptive characteristics are listed in Tables 3 and 4.

The mean risk perception score was 2.78(±0.6) on a 7-point scale. The lowest mean of the predictors of risk perception in COVID-19 was in trust in the government and the highest mean was in personal efficacy (Table 4).

Table 1: Results of calculating quantitative face validity (impact score) of items of the designed instrument

Item	Frequency	Importance	Impact score
Q1: How worried are you personally about the following issues at present? Coronavirus/COVID-19	0.7	4.4	3.08
Q2: How likely do you think it is that you will be directly and personally affected by the following in the next 6 months? - Catching the coronavirus/COVID-19	0.6	4.1	2.46
Q3: How likely do you think it is that your family and friends in the country you are currently living in will be directly affected by the following in the next 6 months? Catching the coronavirus/COVID-19	0.6	3.6	2.16
Q4: How much do you agree or disagree with the following statements? – The coronavirus/COVID-19 will NOT affect very many people in the country I'm currently living in	0.5	3.6	1.8
Q5: How likely do you agree or disagree with the following statements? - I will probably get sick with the coronavirus/ COVID-19	0.7	3.8	2.66
Q6: How much do you agree or disagree with the following statements? - Getting sick with the coronavirus/COVID-19 can be serious	0.6	3.3	1.98
Q7: How much do you feel you understand the government's strategy to deal with the coronavirus/COVID-19 pandemic?	0.6	3.5	2.1
Q8: To what extent do you think scientists have a good understanding of the coronavirus/ COVID-19?	0.5	3.6	1.8
Q9: Have you ever had, or thought you might have, the coronavirus/COVID-19?	0.6	3.1	1.92
Q10: Have you come across information about coronavirus/COVID-19 from: - Friends and family	0.6	3.4	2.04
Q11: To what extent do you think it's important to do things for the benefit of others and society even if they have some costs to you personally?	0.7	2.2	1.54
Q12: The government interferes far too much in our everyday lives.	0.8	2.6	2.2
Q13: How much do you trust the country's politicians to deal effectively with the pandemic?	0.6	2.5	1.5
Q14: How much do you trust each of the following? – Scientists	0.7	3.3	2.31
Q15: How much do you trust each of the following? - Medical doctors and nurses	0.6	3.2	1.92
Q16: To what extent do you feel that the personal actions you are taking to try to limit the spread of coronavirus make a difference?	0.6	3	1.8
Q17: To what extent do you feel the actions that your country is taking to limit the spread of coronavirus make a difference?	0.7	3	2.1

** Correlation is significant at the 0.05 level (2-tailed). ** Correlation is significant at the 0.01 level (2-tailed).*

All predictors were analyzed based on gender variables (the Mann-Whitney U test was used due to abnormal distribution). There was a statistically significant difference between men and women in the mean of collective efficacy (P= 0.032) and the rest were not.

Specifically, people who have had direct personal experience of COVID-19 were different in some predictors of risk perception from those who had no direct experience of disease and social knowledge (p=0.007), trust in science (p=0.001) and trust in medical professionals (p=0.050) in positive direct experience people were significantly more than in people with negative direct experience of COVID-19.

We investigated the determinants of risk perception in regression models. The correlations of demographic variables with risk perception were assessed and gender, as well as education, were significantly associated with risk perception of COVID-19, such that males perceive less risk compared to females (Table 6) and the most important predictors of risk perception in COVID-19 epidemic were gender, education, social knowledge and trust in science (Table 7).

Table 6: Regression output of demographic variables of risk perception in COVID-19

a. Dependent Variable: Risk perception

DISCUSSION

Risk perception is important in determining health-protective behavior. Perception of risk in critical experiences like epidemics is influenced by social, cultural, and contextual factors. Previous experiences such as SARS, influenza, and swine flu epidemic showed that the strategies performed and the results of activities often depend on recognizing the predictors of risk perception and coordinating programs with the important predictors [12]. It should be considered the management of risk perception predictors directs by governments in all programs and activities. The risk perception model recommends in COVID-19 epidemics consist of clusters of variables that correspond to the cognitive tradition (e.g. people's knowledge and understanding of risks), the emotional and experiential tradition (e.g. personal experience), the social-cultural paradigm (e.g. the social amplification of risk, cultural theory, trust, and values), and relevant individual differences (e.g. gender, education, ideology). The mean risk perception score was 2.78(±0.6) in this study which is slightly different from the average risk perception score in other countries. The study of risk perception in ten countries found that the risk perception score of COVID-19 epidemics varied between 4.78 and 5.45 on a 7-point scale, and it is relatively high in countries of the U.K., Spain, and North America. Therefore, in this study, the score of risk perception was significantly lower than in all ten countries. High-risk perceptions may enhance the public's active response to the epidemic. Risk perception is a dynamic process and it changes over time. In this study, more than a year had passed from the beginning of the epidemic, which can be an influential factor in the perception of risk.

In demographic factors, gender was the significant predictor of risk perception. The risk perception score of women was higher than men on all the components of risk perception. Other studies reported the same result and it seems that gender was included as the moderator of risk perception and protective behavior [13]. In similar crises of the past decades, women are constantly seen to be more precautionary behaviors than their male counterparts. Another basic demographic predictor is the level of education of the individual, especially in positive experience persons. In other studies, a high level of educated is more likely to improve the preparedness level and adherence to COVID-19 preventive and control guidelines [14], and poor education was significantly associated with lower risk perception [15], similar to our findings.

The level of education could affect knowledge as well as social knowledge; therefore social knowledge might be an important predictor of risk perception, which was observed in this study. Although studies on COVID-19 have reported associations between social knowledge and risk perception [16], some of them did not find this result [17]. Social knowledge is acquired through socialization and lived experience; however educational guidelines in the media at the national level could affect social knowledge, especially in critical situations such as the COVID-19 epidemic. The basic role of social knowledge in predicting the level of risk perception can be considered in the planning and implementation of national protocols.

This study found that scientific sources were the most trusted sources for COVID-19 information. Similar results were reported in Kwok's study on the COVID-19 pandemic [18] and the prior outbreak of SARS in 2003 [19] and the influenza A (H1N1) pandemic in 2009 [20].

Trust in science and experts in this study was greater than trust in government. The lowest mean of the predictors of risk perception was trust in the government. Trust in the government has been found to influence people's willingness to be accepting preventive activities [21], social limitations [22], and vaccination programs [23]. When people lack the necessary knowledge to evaluate the risk of a hazard, trust becomes an important cue regarding whom to believe and behavior [24]. People need to rely on scientists, professionals, and government agencies to listen and realize the information and the people's trust in these sources might be an important factor contributing to people's acceptance of the difficult precautionary measures needed to eradicate a pandemic [25].

This study might be consisting of some limitations. It should be noted that the study population was limited to those who were referred to the hospital. These people may not be a perfect example of the general population, and it is better to do such research at the national level and with diverse populations. The duration of the research was limited, and it is better to do this research several times.

CONCLUSION

People's perception of the risk of COVID-190 depends on several various factors, the most important of which were gender, level of education, social knowledge, and people's trust in science. It is recommended that studies be performed with larger and heterogeneous populations and longer time.

Abstract: *We aim to introduce a 2022 update on CHD (carcinoid heart disease) considering a multidisciplinary perspective. This is a narrative mini-review. We searched English, full-length papers (PubMed). Inclusion criteria: original articles regardless of the level of statistical significance. We identified 44 papers and manually selected those with CHD, as follows: 8 original studies, 1 case series (N=9 patients), 16 case reports (N=1 patient/paper), and a total of 1,030 patients on published studies. The most remarkable results are the longest period of enrolment of 3-4 decades; CHD ratio among carcinoid syndrome of 37%; 30-day mortality post-cardiac surgery of 12%; median survival in CHD from 1.3 to 3.9 years (more than 2 years if valve intervention is provided); most useful prognostic markers: 5HIIA, NT-pro-BNP, but, potentially, chromogranin A. The specific protective role of somatostatin analogs against developing CHD is yet to be determined. CHD in the absence of carcinoid syndrome/liver metastasis may be related to ovarian NEN (neuroendocrine neoplasia) with a better outcome if prompt intervention. Remarkably, 3 guidelines are released regarding CHD on behalf of ENETS (European Neuroendocrine Tumor Society), and ESC (European Society of Cardiology). CHD still represents a most challenging entity situated at the crossroads of surgery, cardiology, oncology, endocrinology, and gastroenterology.*

Keywords: *carcinoid heart disease, neuroendocrine, serotonin, neuroendocrine neoplasia, carcinoid syndrome, 5HIIA, valve, tricuspid, echocardiography*

INTRODUCTION

The complex field of neuroendocrine neoplasia (NEN), a rare condition with an annual incidence of 2 to 5.1 cases per 100,000 individuals, represents one of the most spectacular domains with massive recent progress from a multidisciplinary perspective [1,2]. The two main direct cardiac complications of NENs' evolution are either heart metastasis or carcinoid heart disease (CHD), also, recently named carcinoid valvular heart disease [3,4]. Primary cardiac NENs are mostly uncommon [5]. While myocardial and pericardial NENs' spreading is unusual (representing less than 1-3% of NENs-related metastases), CHD represents the hallmark of a very severe disease, typically embracing a very poor outcome [6,7]. The advances in cardiac surgery and interventional once-cardiology which have been registered within the latest years improved the overall CHD prognostic, as recently seen in other cardiac surgical procedures [8,9].

CHD is related to hormonally active NENs that increase overall morbidity and mortality; nevertheless, valve intervention might associate with numerous benefits, but carriers of such interventions display additional risks, including the need for post-operative pacing or connected infectious risks [10,11]. The statistical confirmation that the surgical approach to CHD improves survival is currently based on observational data rather than controlled studies [12].

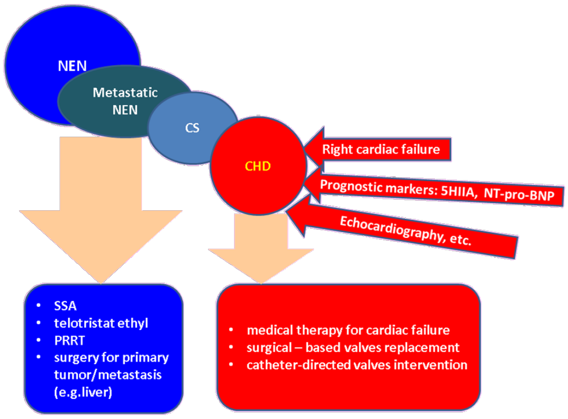
The pathogenesis of CHD is still poorly understood. However, the presence of CHD is closely correlated with abnormal levels of biomarkers (blood and urinary neuroendocrine markers, also, named vasoactive substances which are more than 40 types, despite not testing all of them in daily practice), especially serotonin, and its urinary metabolite 5-HIIA (5-hydroxy-indole acetic acid), but, also, chromogranin A, neuron-specific enolase, etc. which serve as diagnostic tools and prognostic markers as well as part of the surveillance protocols [13-15]. Novel biomarkers like those based on mRNA transcript are currently under development for daily practice implementation [13]. Cardiac imaging is essential for recognizing CHD, from traditional ultrasound to advanced techniques such as speckle-tracking echocardiography, 68 DOTA peptide PET-CT (Positronic Emission Tomography – Computed Tomography) scans, and cardiac magnetic resonance or CT [12,16-18].

CHD almost exclusively targets the right cardiac side with consecutive heart failure, but in the early stages, the complication might be underdiagnosed [19]. The left side of the heart is usually not affected (unless abnormal intra-cardiac shunts) because the fact that the main contributor of CHD, namely serotonin (5-hydroxytryptamine), but, also, histamine, bradykinins, and tachykinins, are enzymatically inactivated into pulmonary bloodstream [19]. Remarkably, in 2018 three cases of quadruple valve replacement were reported in addition to the prior four concerning CHD, which represents exceptional situations in NEN-CHD pointing out that the left heart side may be affected, as well [20].

Usually, at the moment when CHD is identified, the patients already have clinically manifested NEN in terms of traditional carcinoid syndrome (flush, diarrhea, wheezing, loss of appetite and malnutrition, non-specific abdominal pain or cramps, hypotension, telangiectasia, edema, etc.) that is presented in correlation with liver metastases, grossly affecting 30-40% of all NENs [21]. Most patients with CHD are aged between 50 and 70 years (males being slightly more affected than females), and present chronic fatigue and dyspnea, independent of carcinoid syndrome (but may be initially misdiagnosed as carcinoid syndrome or even carcinoid crisis) [19]. The most frequent type of NEN causing CHD is gut-derivate (noting that the small intestine is the most frequent NEN up to 65-67% followed by lung NEN of 25%) and approximately one out of five or two cases (depending on the studied population) is prove to develop CHD which finally influence the prognostic even more than the primary tumor growth itself (in some cases) [12,22]. One meta-analysis from 2021 (including 9 studies, N=416 adults with NEN, mean age of 63 years, 53% males) showed that 75% of CHD – related NENs originate from the small intestine and colon, and 98% of them have synchronous hepatic metastases. Tricuspid regurgitation was confirmed in 97% of individuals of different severities, respective 72% concerning pulmonary valve, while right heart failure was identified in 48% of all cases. After having a valve replacement (99% of tricuspid, and 59% of pulmonary valve), a 30-day mortality of 9% was identified (with a median post-surgery survival of 3 years) which points out an acceptable safety profile of valves intervention in CHD [23].

Overall, the multidisciplinary management of CHD includes cardiologic therapy for heart failure, the control of serotonin excess by using high doses of somatostatin analogs such as octreotide or lanreotide (and/or telotristat ethyl) that act on tumor growth as well, peptide receptor radionuclide therapy in addition to surgery for primary tumor and metastases, especially at the liver site (if feasible) to reduce the tumor burden, and, finally, surgical – based valves replacement or catheter-directed valves intervention in selected patients, depending on various criteria that take into consideration the underlying NEN, the heart status, and the access to cardiac surgery or interventional cardiology [24-28]. Globally, patients with carcinoid syndrome (thus metastatic NENs) and CHD have a more severe prognostic when compare to those without CHD, knowing that NEN individuals with clinically manifested carcinoid syndrome have a more severe prognostic versus those carcinoid free [28,29]. Valve intervention in CHD improves long-term outcomes despite the current peri-operatory mortality rate being considered at 10-20% [29]. Of note, there is no specific medication for CHD other than the medical approach for the originating tumor and associated hormonal panel (NEN's management), on one hand, and cardiologic therapy for heart failure in addition to interventional procedures targeting the affected valves [28-30] (Figure 1).

Figure 1: Sneak peek – carcinoid valvular heart disease



NEN
Metastatic NEN
CS
CHD
Right cardiac failure
Prognostic markers: 5HIIA, NT-pro-BNP
Echocardiography, etc.
SSA
telotristat ethyl
PRRT
surgery for primary tumor/metastasis (e.g.liver)
medical therapy for cardiac failure
surgical – based valves replacement
catheter-directed valves intervention

NEN = neuroendocrine neoplasia; CS = carcinoid syndrome; CHD = cardiac heart disease; 5HIIA = 5-hydroxyindoleacetic acid; NT-pro-BNP = NT-pro-brain natriuretic peptide; SSA = somatostatin analogues; PRRT = peptide receptor radionuclide therapy

MATERIALS AND METHODS

Aim

Our purpose is to introduce a 2022 update on CHD considering a multidisciplinary perspective.

Method

This is a narrative mini-review of literature. We searched English, full-length papers published in 2022 concerning journals indexed in PubMed (by using the terms "carcinoid heart disease"). Inclusion criteria are represented by original articles particularly/specifically addressing CHD (in vivo) regardless of the level of statistical significance (original studies or case reports/series). Exclusion criteria: papers considering heart metastasis in NENs or primary cardiac NENs.

According to mentioned methodology, we identified 44 papers in 2022, and manually selected those with CHD, as follows: 8 original studies, 1 case series (N=9 patients), 16 case reports (N=1 patient/paper), a total of 1,030 patients on published studies, in addition to 8 reviews, 3 guidelines (one with duplicate). We excluded 3 articles concerning non-CHD, one in vitro study, and 3 papers regarding withdrawal (Figure 2).

CLINICAL STUDIES PUBLISHED IN 2022 CONCERNING CHD (accessed via PubMed)

We identified 8 original studies in 2022 (Table 1). A multicenter, retrospective study on 275 patients analyzed the clinical presentation and the outcome in NENs, confirming that more than one-third of the individuals with carcinoid syndrome are affected by CHD. All the patients had carcinoid syndrome (mean age of 57 years, aged between 21 and 84 years; metastatic disease was found in 94.6% of cases). CHD was identified in 37.3% of them (N=104) by using echocardiography, with the tricuspid valve being the most affected cardiac site, single or in combination with other valves. CHD correlated with a poor prognostic in individuals with carcinoid syndrome (similarly, male sex was found to be a risk factor); median survival in the studied population was of 9 years) [31].

Figure 2: The articles included according to the methodology of research

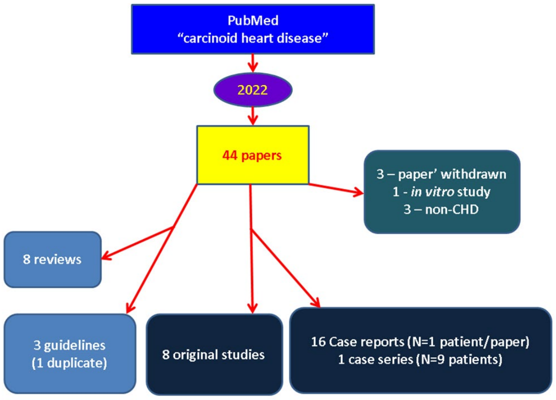


Table 1: Original studies published in 2022 considering carcinoid heart disease

First author/ Reference number	Type of Study	Number of patients	Results
Bergsten J [32]	retrospective (1986 - 2019)	60	30-day mortality (after cardiac surgery)=12% median post-operatory survival = 2.2 years
Levy S [34]	retrospective (1984 - 2021)	84	median survival since CHD diagnostic varying from 1.3 to 3.9 years
Levy S (bis) [35]	validation (case-control) study (1984 - 2021)	114	NT-pro-BNP has the best predictive value for CHD
Kostiainen I [36]	cross-sectional cohort study	65	low rate of CHD (5%) highly sensitive value of echocardiography (not BNP)
Shah HA [33]	retrospective study (2010 - 2019)	17	a 35% decline rate of 5-HIIA in association with liver function improvement
Macfie R [39]	retrospective study (2001 - 2021)	282	overall survival is lower in CHD *versus* non-CHD (N1=40 *versus* N2=242, p<0.001) valve replacement improves survival in CHD + inoperable liver metastasis
Konsek-Komorowska SJ [38]	retrospective study	108	chromogranin A inversely correlates with overall survival (p<0.05) in patients with carcinoid syndrome overall survival is lower in CHD *versus* non-CHD + carcinoid syndrome (67.22 versus 73 months)
Fijalkowski R [31]	retrospective study	275	prevalence of CHD 37.3% among patients with carcinoid syndrome overall survival is lower in CHD *versus* non-CHD

Abbreviations: CHD=cardiac heart disease; BNP=brain natriuretic peptide; N=number of patients

Bergsten J. et al. studied 60 patients (between 1986 and 2019, a total of 3 decades) with a median age of 64 years with CHD and cardiac surgery (N1=42 persons underwent both tricuspid and pulmonary valve replacement; N2=18 individuals had only tricuspid valve replacement with/without pulmonary valvotomy). The procedures (which exclusively used bioprosthetic valves) associated a 30-day mortality of 12%; and a median post-operatory survival of 2.2 years (a maximum of 21 years; statistically significantly higher in N1 versus N2, respective of 3 versus 0.9 years, p=0.02). A most useful tool of prognostic was echocardiography, either as a pre-operatory assessment (but with the limitation of underestimating pulmonary involvement) or post-operatory surveillance. Additional poor prognostic markers are high pre-surgery levels of 5-HIIA and NT-pro-BNP (NT-pro-brain natriuretic peptide). Overall, the double valve is superior to single tricuspid replacement [32]. Moreover, a retrospective UK study (between 2010 and 2019) on 17 patients with CHD who became candidates for valve replacement surgery had a single valve procedure (3/17) versus double valve (13/17), respective triple valve (1/17). Post-operatory, a 35% decline of 5-HIIA witnesses the improvement of general status in association with hepatic function recovery which suggests an indirect benefit of cardiac surgery [33].

Levy S. et al. introduced a cohort study on 84 patients with CHD (58% males) followed for 4 decades (between 1984 and 2021) at Netherlands Cancer Institute; the median age of NEN confirmation was of 62.3 years with a consecutive CHD diagnostic after a median of 1.1 years and an associated median survival varying from 1.3 to 3.9 years (considering the patients who were most recently admitted when valve replacement surgery was more often applied). Prognostic markers are NT-proBNP (positively correlated with tricuspid regurgitation), respective to the implementation of valve replacement surgical procedures (which increases the survival rate) [34]. The same researchers conducted a validation (case-control) study on CHD – associated biomarkers. 114 individuals (N1 with CHD versus N2 without CHD) showed similar age (median age of N1 – 57.9 years, respective of N2 – 59.7 years, p=0.29). Among studied assessments like circulating serotonin, activin A, sST2 (soluble suppression of tumorigenicity 2), CTGF (connective tissue growth factor), and NT-pro-BNP had the best predictive value for CHD in individuals with high serotonin [35].

As opposed to these results, we mention a cross-sectional cohort study on 65 patients with small intestinal NETs (neuroendocrine tumors) (45% with carcinoid syndrome and 5% with CHD). The results showed that both categories had a statistically significant increase in hepatic tumor load, serum levels of chromogranin A, and urinary 5HIIA when compare to the patients without carcinoid syndrome (p<0.005). However, the authors identified a lower rate of CHD (5%) than expected in persons with carcinoid syndrome (30-50% – according to data from the literature). Moreover, they did not confirm the predictive value of proBNP but identified the highly sensitive value of echocardiography in subjects with elevated chromogranin A and 5HIIA [36].

Another classical biomarker in NENs is chromogranin A, very sensitive, but less specific [37]. A retrospective study focusing on blood chromogranin A values (N=108 patients with carcinoid syndrome; N'=84 individuals were followed-up and 27 of them complicated with CHD) showed that its increased levels inversely correlate with overall survival (p<0.05) in patients with carcinoid syndrome. Also, the presence of CHD is statistically significantly associated with a reduced overall survival (67.22 versus 73 months in patients with carcinoid syndrome but CHD-free) [38].

Some authors consider the protective effect of somatostatin analogs like octreotide for CHD, but a large study on 282 patients with carcinoid syndrome (between 2001 and 2021) did not sustain this observation. Overall survival was lower in patients with CHD versus non-CHD (N1=40 versus N2=242, p<0.001). Considering the patients with inoperable hepatic metastasis, the survival rate was lower in patients without undergoing valve replacement when compared to the individuals with CHD and cardiac surgery or the individuals CHD-free [39]. Similarly, we mention a case series of 9 subjects with NEN who followed for 39 months; initially, the patients were CHD-free and started therapy with somatostatin analogs (median time from NEN diagnostic to therapy initiation of one month; median time from starting the medical treatment to CHD confirmation of 23 months) [40]. As far as we currently know, we cannot predict that using somatostatin analogs is a protection factor against CHD, but, of course, this medication has a proven effect in controlling the hormonal and tumor burden [41].

INTERESTING CASE REPORTS

We identified according to our methodology 16 case reports (a total of 16 patients with CHD). We mention the case of a 70-year-old female with torrential tricuspid regurgitation due to CHD regarding an ovarian teratoma with neuroendocrine differentiation. The subject had a heterotopic tricuspid valve replacement with a stable disease within the following 6 months. Mostly particular, the patient did not experience carcinoid syndrome, and neither imaging assays proved any metastatic NEN (including hepatic) after gynecological surgery [42]. Similarly, another case of a large insular primary ovarian NEN was reported on a 40-year-old female admitted for virilization syndrome in association with unexpected CHD – related heart failure; the panel of increased neuroendocrine markers improved after gynecological intervention, but CHD aggravated even in the absence of liver metastasis requiring valve replacement within 6 years [43]. This scenario is extremely unlikely among the typical evolution of NENs, neither ovarian NEN is recognized as a common source of serotonin over-production. However, ovarian carcinoid tumors are among the rarest forms of CHD in the absence of carcinoid syndrome and/or liver metastases, thus their early removal massively improves the survival rate and does not follow within the general frame concerning the very poor outcome in CHD-NENs [44-46].

adequate diagnostic/recognition when she was identified with CHD and had cardiac surgery. The identification of primary NEN was after the intervention for CHD [47]. This case brings out at least two atypical aspects: CHD in young adults, as prior mentioned, which is rather atypical unless a clear genetic background is present, and CHD diagnostic before confirmation of primary NEN [48]. Generally, one-third of NENs remain with unknown primary sources [49]. Theoretically, younger patients with CHD and NEN might have a better post-cardiac surgery prognostic, but further statistical evidence is needed.

A 44-year-old male with neurofibromatosis type 1 had a 6-year history of gastric NET with hepatic metastasis. He was admitted for sensory neuronopathy and a meningocele. After glucocorticoid treatment was empirically initiated, additional decompressive laminectomy was done, but the patient soon developed CHD with a fatal outcome within 3 months (due to pneumonia) [50]. Of note, currently, we do not know the potential role of glucocorticoids (probably recommended for incidental co-morbidities) in aggravating CHD. Moreover, there are no consistent data to point out that individuals with genetic syndromes underlying NEN have a higher risk of developing CHD [51].

As consideration amid the recent COVID-19 pandemic, we mention one case of a 55-year-old male who delayed the presentation and was admitted for severe CHD which was confirmed synchronously with a high serotonin-producing primary NEN [52]. Another case brings out the particular aspects of cardio-oncology practice following valve replacement in subjects with CHD [53]. This is the case of a 58-year-old female who experienced a carcinoid crisis peri-operatory [54]. Another aspect concerns the post-surgery risks, for instance, a 77-year-old woman was offered a successful ablation therapy for recurrent atrial flutter developed after the surgical procedure of replacing the tricuspid valve [55]. Moreover, another case of an 81-year-old male introduces the idea of consecutive interventions in CHD considering the right side of the heart (severe pulmonary regurgitation was successfully approached by trans-catheter implantation 4 years after initial surgery for tricuspid) [56].

DISCUSSIONS

Pathogenic traits of CHD

Hedinger syndrome, tricuspid insufficiency in addition to pulmonary stenosis due to CHD still represents a challenging condition nowadays [57]. CHD is a progressive condition in subjects with carcinoid syndrome where the right side of the heart is transformed in terms of fibrosis, degeneration, inflammation, desmoplastic reactions causing valvar dam-age (stenosis or regurgitation), and cardiac insufficiency [58,59]. The formation of plaque-like deposits (myo-proliferative plaques) on endocardial areas of the valves and subvalvular system impairs the blood flow dynamics [60-62]. Similarly to CHD, mesenteric fibrosis might develop in individuals with carcinoid syndrome [60]. Common pathogenic factors are described like TGF-β (Transforming growth factor beta) or PDGF (platelet-derived growth factor), etc [60].

The clinical approach of CDD

The main predictors of CHD are an advanced stage of NEN with high levels of circulating serotonin but mostly increased 24-hour urinary 5HIIA in addition to the presence of carcinoid syndrome and other clinical features [63-65]. Other collateral elements may involve particular cardiac anatomy, for instance, patent foramen ovale is reported in half of the individuals with CHS (twice more frequently than in the general population) which causes a right-to-left shunting [66,67]. Intra-cardiac shunt explains the left heart involvement in CHD as one case was published in 2022 with four valves involvement [68,67].

Since initially, CHD is subclinical or completely asymptomatic, a strategy of periodic check-ups is necessary, including performing differential diagnostics with other complications of NENs [60,63,69]. Cardiac imaging represents a strong point in CHD management. Ultrasound is useful for serial evaluations and early assessment; CT exams might show various elements like early contrast opacification of inferior cave vein as an indicator of tricuspid regurgitation; modern imaging procedures like 68Ga-DOTATATE PET are helpful for adequate positive diagnostic, especially for cases with a low index of suspicion, when a differentiation with myocardial metastasis or non-NEN incidental conditions is needed [70-72]. One case from 2022 introduced 203Pb-VMT-α-NET Scintigraphy as a new alternative to PET/CT [73].

Full blown picture of heart valve disease – associated clinical manifestations and related cardiovascular and pulmonary complications of NENs including carcinoid crisis represents a sign of advanced disease and prompt multi-disciplinary intervention is required [74,75]. The overall experience with cardiac surgery for CHD is limited when compared to many of the non-CHD causes, thus there are still some areas of open discussion like predictors of successful intervention, the timing of the procedure, criteria of candidates selection, the type replacement (single or double valve) [76-79].

Key messages on behalf of highly specialized medical and surgical societies

In 2022 three papers of major importance were released concerning CHD. European Neuroendocrine Tumor Society (ENETS) published excellent “guidance” regarding carcinoid syndrome and CHD. We mention a few major aspects: NT-proBNP remains the most important marker of CHD at the first-ever diagnostic (in patients who experience high serotonin status with or without clinical manifestation like carcinoid syndrome) and during follow-up. A cutoff value of 260 pg/mL indicates further investigations with echocardiography. In terms of ultrasound, the transthoracic approach is indicated, stress echocardiography might not bring additional information; while inadequate ultrasound data (including the evaluation of pulmonary vein damage) or planning for cardiac surgery may require supplementary imaging procedures like cardiac CT or magnetic resonance. Once identified, CHD requires serial NT-proBNP assays and cardiac ultrasound every 6 to 12 months, noting that sudden progress might occur anytime. Surgery (bioprosthetic valves are advised) should be done in severe CHD with more than 1 year of expected post-surgery survival; some specific criteria are recommended considering the adequate timing of intervention which should not be delayed. Double valve (tri-cuspid and pulmonary) replacement is better than a single one. Minimally invasive procedures are not yet studied enough [80]. Additionally, ENETS introduced a "synoptic" concerning the major role of echocardiography in CHD [81]. A collaboration of ESC (European Society of Cardiology) with other societies provided a guideline on cardio-oncology, also, addressing CHD. We mention some aspects, such as, for instance, echocardiography is recommended in patients with clinical evidence of CHD, carcinoid syndrome, and high BNP followed by a check-up every 3 to 6 months (level IB). BNP is assessed at baseline and every 6 months (level IB). A specific preparation is required considering the surgical/interventional risk of triggering a carcinoid crisis. Valve replacement, as in the ENETS guide-line, is recommended in patients with an expected survival of more than 1 year after intervention if they have symptomatic CHD or asymptomatic CHD (tricuspid or pulmonary) but with progressive dysfunction (level IC, respective IIaC) or severe mitral and/or aortic involvement in symptomatic cases (level IC) [82,83].

CONCLUSIONS

CHD represents a most challenging entity situated at the crossroads of surgery, cardiology, oncology, endocrinology, and gastroenterology. Until a few years ago, CHD was synonymous with a very severe form of NEN/carcinoid syndrome, with an expected poor outcome and limited resources. Recent cardio-oncology progress in addition to multiple shaped interventions for NEN allows a new level of approach in CHD to the benefit of the patients. However, many aspects are still open issues even in 2022.

List of Abbreviations

5-HIIA = 5-hydroxyindoleacetic acid
NEN = neuroendocrine neoplasia
CHD = carcinoid heart disease
NT-pro-BNP = NT-pro-brain natriuretic peptide
PET-CT = Positronic Emission Tomography – Computed Tomography
TGF = Transforming Growth Factor
PDGF = platelet-derived growth factor
NET = neuroendocrine tumor
NEN = neuroendocrine neoplasia
sST2 = soluble suppression of tumorigenicity 2
CTGF = Connective Tissue Growth Factor
ENETS=European Neuroendocrine Tumor Society
ESC=European Society of Cardiology

Abstract: *Collision tumors, rare neoplasms underlying two distinct histological types of carcinomas (with different origins) separated by normal tissue, are described in many organs including the thyroid gland, but to a lesser extent. We aim to overview the current published data concerning collision tumors of the thyroid (CTT). This is a narrative review considering papers published on PubMed through a search starting from the terms "collision" and "thyroid". Inclusion criteria are full-length articles, the English language, the timeline from inception to December 2022, and original studies with different levels of statistical evidence. We followed the main types of thyroid carcinomas: differentiated thyroid carcinoma of papillary and follicular type, anaplastic/ undifferentiated/poorly differentiated carcinoma, respectively medullary thyroid carcinoma. We identified 92 papers based on the mentioned key words criteria. We excluded 54 papers (reviews or non-thyroid CTT or other topics outside our purpose). We included in the final analysis 38 papers: 34 case reports (1 patient per paper), 2 case series (2 individuals per each article), one case series of 3 subjects, and a single study of retrospective type (including 21 subjects) – a total of 62 patients on published cases which represents the largest study on published cases to our knowledge (according to our methodology).*

Keywords: *collision, thyroid, thyroid cancer, papillary carcinoma, follicular carcinoma, medullary thyroid cancer, thyroidectomy, pathological report*

INTRODUCTION

Collision tumors, rare neoplasms underlying (at least) two distinct histological types of carcinomas (with different origins) separated by normal tissue (and no mixture areas), are described in many organs (for instance, lung, stomach, breast, and ovary, etc.) including the thyroid gland, but to a lesser extent than seen in others sites (affecting less than 1% of all thyroid malignancies) [1-3]. The most common combination is papillary and medullar carcinomas, but any type of primary thyroid malignancy is reported in collision with a secondary spreading to the thyroid from a non-thyroid primary cancer or another primary type [4-6].

Collision tumors of the thyroid (CTT) are regarded as challenging in terms of recognition, poor outcome elements, and particular behavior in addition to the fact that there are still areas of the unknown regarding this chapter on thyroid neoplasms [7-9]. A distinction with composite tumors should be done (where the same mutation causes histologically different entities) [10-12]. Also, metachronous tumors (syndromic or not) represent a different category [13-14].

We aim to overview the current published data concerning CTT**.**

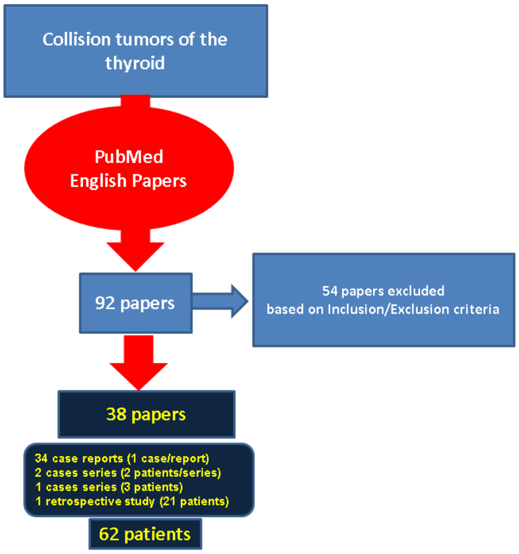
MATERIALS AND METHODS

This is a narrative review considering papers published on PubMed through a search starting from the terms "collision" and "thyroid". Inclusion criteria are full-length articles, the English language, the timeline from inception to December 2022, and original studies with different levels of statistical evidence. Exclusion criteria are non-thyroid collision tumors, non-English papers, and reviews. We followed the main types of thyroid carcinomas: differentiated thyroid carcinoma of papillary and follicular type, anaplastic/undifferentiated/ poorly differentiated carcinoma, respectively medullary thyroid carcinoma**.**

RESULTS

We identified 92 papers based on the mentioned key words criteria. We excluded 54 papers (reviews or non-thyroid CTT or other topics outside our purpose). We included in the final analysis 38 papers including 34 case reports (1 patient per paper), 2 case series (2 individuals per each article), one case series of 3 subjects, and a single study of retrospective type (including 21 subjects) – a total of 62 patients on published cases which represents the largest study on published cases to our knowledge (according to previously mentioned methodology) (Figure 1).

Figure 1: The method of research considering collision tumors of the thyroid



Collision tumors of the thyroid

1 cases series (3 patients)
1 retrospective study (21 patients)
62 patients

Papillary thyroid carcinoma

Papillary thyroid carcinoma is the most frequent histological type in CTT, but, generally as a single entity, it represents the most common thyroid neoplasia [15]. Apart from the most often association of medullary thyroid neoplasia, follicular malignancy is reported as well [16-19]. The combination with thyroid metastasis (typically from lung, breast, or renal cancers, etc.) is reported at the level of case reports (the spreading may be by local extension or via blood mainstream) [20-21]. For example, a case from 2007 introduced a CTT consisting of metastasis from lung adenocarcinoma and papillary thyroid cancer in a 63-year-old female [20]. A case report from 2021 included a 60-year-old female who was identified with the same carcinoma and metastasis from osteosarcoma within a CTT. This is the first case with bone origin as the primary source reported in a CTT [21]. The combination with a second primary cancer which is not originating from the thyroid is also reported. We identified a single case of a 67-year-old male who was diagnosed with a CTT associated a papillary thyroid cancer (with lymph node metastases) and parathyroid carcinoma clinically manifested with primary hyperparathyroidism [22]. The co-existence of a squamous cell carcinoma was reported, as well, originating from different sites or of unknown origin [23-27]. In 2004, a most unusual association with metastatic liposarcoma was published (this represents a most unique combination) [28].

Follicular thyroid carcinoma

This is the case of a 62-year-old female with follicular carcinoma (with capsular and vascular invasion) in association with a mucoepidermoid carcinoma and distant metastasis. Immunohistochemistry report might identify the mucoepidermoid differentiation of follicular malignancy over a different histological type (like mucoepidermoid malignancy) [29]. Hürthle cell carcinoma (regarded as a type of follicular group of differentiated thyroid cancers) is reported in less than 3% of thyroid malignancies, with the same ratio (of 3%) being reported for medullary thyroid carcinoma, as well. Their combination was identified on a 70-year-old female as a CTT (of note, the medullary cancer was intra-thyroidal, while the lymph nodes extension was derivate from Hürthle cell carcinoma) [30].

Interestingly, one retrospective study on 8 patients diagnosed with a primary thyroid malignancy identified the co-presence of the second histological type, meaning a follicular thyroid adenoma in association with papillary thyroid carcinoma (7/8), respectively medullary thyroid carcinoma (1/8) [31]. However, the current definition of CTT includes two malignant tumors, either primary or secondary, not a benign one like a follicular adenoma (which cannot be differentiated from a follicular carcinoma through the cytological report and it requires histological assessment) or a non-tumor – related cyst [31,32].

Medullary thyroid carcinoma

CTT may concern the thyroid gland and/or associated lymph nodes [33,34]. For instance, there is a case published in 2021 involving a 27-year-old male presenting CTT at lymph nodes (central compartment) from papillary thyroid cancer and non-syndromic medullary thyroid cancer. The growth speed was evaluated and the authors suggested that it may be similar to what we prior know concerning each of the two malignancies [35]. Generally, collision metastasis (mostly at cervical lymph nodes) is rarely reported in the absence of a thyroid tumor itself. We identified two papers concerning collision metastasis from papillary thyroid cancer and breast malignancy in female subjects [36,37]. In another case, a 73-year-old male was admitted for collision metastasis (cervical lymph nodes) from squamous cell carcinoma of nasal origin and B-cell lymphoma [38]. A previous report from 2009 included a lymph node spreading from a primary follicular malignancy and a squamous cell carcinoma of unknown origin [39]. Moreover, we mention the case of a 47-year-old male with collision metastasis from oral tongue–related squamous cell carcinoma and accidentally detected thyroid papillary carcinoma [40].

However, we currently do not have enough statistical evidence to compare the evolution in CTT versus non – CTT cases. The largest study particularly addressing CTT is a retrospective analysis that included the experience from 2009 to 2019 (a 10-year experience) on a tertiary care cancer. CTT (medullary + papillary) represented 4.7% of the medullary cancer series (N=21 individuals, the sex ratio of 1; mean age of 45.33 years, range between 26 and 77 years). 66.66% of the papillary cancers were situated at the right thyroid lobe; 85.7% of them were of micro-papillary type. The mean size of medullary cancer was three times larger than differentiated thyroid tumors. The contribution to lymph node spreading (which was confirmed in 76.2% of cases) was done by medullary type (87.5%), papillary cancer (12.5%), respectively both malignancies (12.5%) [41].

Anaplastic, undifferentiated, and poorly differentiated thyroid carcinoma

In 2022 Gupta RK. et al. reported the case of a 55-year-old female with a most unusual CTT: anaplastic thyroid malignancy (osteoclastic variant) and primary squamous cell carcinoma, each affecting a different thyroid lobe in addition to distant metastases at the level of bone, muscle and lymph nodes. However, according to WHO (World Health Organization) 2022, these two types are parts of the same malignancy spectrum thus their combination is nowadays regarded as a CTT-like lesion [42].

The "late anaplastic shift" theory concerns the identification of anaplastic thyroid carcinoma on a subject with a long history of differentiated thyroid carcinoma (either papillary or follicular) [43]. However, the synchronous identification of a differentiated tumor in association with a poorly differentiated cancer respecting a border area between them is consistent with the current concept of CTT. Here we mention the case published in 2021 by Vlad M. et al. (a 56-year-old female admitted amid the COVID-19 pandemic with a post-thyroidectomy confirmation of anaplastic cancer on the left lobe and lymph nodes spreading and a papillary micro-carcinoma on the right lobe) [44].

The presence of two highly aggressive malignancies in CTT makes the prognostic extremely severe. There is the case of a 63-year-old female confirmed with a triple CTT: poorly differentiated carcinoma, papillary carcinoma (classical and hobnail variant – this is the first case report underlying this subtype in CTT), and oncocytic (Hürthle cell) carcinoma. The hobnail pattern has been reported in anaplastic and poorly differentiated thyroid malignancies, representing a sign of a very aggressive profile with rapid evolution [45].

DISCUSSION

Pathogenic loops in collision

The field of thyroid surgery is extremely complex, while the domains of pathological reports underlying thyroid neoplasia are also extremely vast and dynamic [46-48]. The collision phenomenon has been described at many levels within multiple organs of the human body [49]. "Chance" theory is one pathogenic hypothesis [41]. CTT might be underdiagnosed, especially micro PTC [41]. Fine needle aspiration (cytological report) might not identify both tumors. However, immunohistochemistry and molecular studies might help the diagnostic [50].

Whether different immune or genetic co-morbidities might act as a trigger or epigenetic elements for CTT development there is still an open question. We mention a case of CTT (papillary and medullary neoplasia) in a 46-year-old female with multiple sclerosis and prior therapy with interferon. This is the first case of CTT on a patient with this neurologic condition (published in 2020) and there is still missing information about a potential pathogenic loop [51].

Common genetic background of both tumors underlying CTT is reported in some cases. For instance, there is the case of a 69-year-old woman with Hürthle cell carcinoma (on the right lobe) and multi-centric papillary cancer (on both thyroid lobes), associated with BRAF mutations (V600E gene) [52].

Also, in 2010, a case of non-multiple endocrine neoplasia medullary cancer in addition to papillary malignancy underlying CTT was reported in a female carrying a particular RET mutation (familial medullary thyroid cancer) [53]. A RET somatic point mutation in association with mixt medullary–papillary (including a follicular variant of papillary cancer) neoplasia was described in a 59-year-old male (a case published in 2007) [54]. Earlier data also suggest this theory [55]. Moreover, the co-presence of granulomatous inflammation in a case of papillary–medullary malignancy might represent the hallmark of common pathways [56].

Early reports of CTT

Of historical note, we identified the first report regarding CTT on PubMed in 1977 (non-English paper) [57]. The first English paper concerning a single case with medullary and papillary neoplasia is dated 1989 [58]. The first case series (2 out of 3 cases) on PubMed with the same mix of neoplasia is published in 1994 [59]. The first CTT with collision metastasis published in a PubMed – indexed journal dates from 1996 [60]. The first triple CTT (on PubMed) was reported on a 27-year-old female with papillary, follicular, and medullary carcinoma [61].

The literature-based analysis

Overall, we identified 62 cases on published data concerning CTT, thus we may say that this particular entity remains at the level of case reports. However, paying attention to this most unusual neoplasia might improve the prognostic and help early detection of at least one of the tumors. With one exception, all cases included at least one differentiated thyroid malignancy, either papillary or follicular (including 3 cases of Hürthle cell/oncocytic carcinoma). Five reports were consistent with the concept of collision metastasis concerning local lymph nodes (near the thyroid). 16/38 articles included medullary thyroid cancers. Based on these data, following differentiated (papillary being the most frequent) and medullary types, elements of squamous cell carcinoma originating from different organs were more frequent than anaplastic/poorly differentiated carcinoma. As mentioned, the most uncommon elements in CTT were: metastatic liposarcoma and osteosarcoma, respectively, and parathyroid carcinoma. All reported cases are adults (we did not identify any pediatric cases). The age varied between 26 and 88 years. More than half of the papers included female patients, but the single study we have so far reported an equal prevalence between males and women (Table 1).

Table 1: Published cases on collision tumors of the thyroid according to our methodology; the cases are displayed from the most recent starting with 2022 (please see references in the text according to first column indices)

We currently do not know if any data concerning the age or the sex of the subjects should be regarded as risk factors. In addition to the lack of poor survival indices (which are relevant in metastatic cases, those with late diagnostic, and anaplastic/ poorly differentiated tumors), the underlying mechanisms are controversial and we need further histological, molecular, and genetic studies.

CONCLUSIONS

The current limits of the CTT field are correlated with the small size of published data until the present time. We still need markers of poor prognostic. Awareness is essential for early detection with a consecutive potential improvement of the outcome.

Abstract: *The recent increase in life expectancy is the main argument for a better understanding of the pathophysiological mechanisms underlying aging. These, once known, can provide possible links to therapies to prevent aging or slow down the process. Normal aging is associated with a progressive decrease in the glomerular filtration rate. Accurate estimation of GFR in the elderly is under the suspicion of multiple errors mainly due to sarcopenia and decreased protein intake. Differentiation between chronic kidney disease and the physiological decline of GFR might be a challenge in clinical practice and this has consequences on the evolution and treatment of the numerous comorbidities of the elderly. The current trend to use non-invasive diagnostic techniques explains the need to identify a serological marker to help differentiate between decreased GFR secondary to kidney aging or the development of chronic kidney disease.*

Keywords: *elderly, normal kidney aging, chronic kidney disease*

INTRODUCTION

Globally, there is a progressive aging of the population.

According to the United Nations Report, 1 in 11 people was over 65 years old in 2019 and it is estimated that in 2050, 1 in 6 people will be this age [1].

The aging process affects the whole body and is characterized by structural changes and functional decline in all organs, leading to an increased incidence of many diseases considered "specific to the elderly". Among these changes, the aging-associated alterations in both structure and function of the kidney are particularly important, having consequences on the evolution and treatment of the numerous comorbidities of the elderly.

Accurate quantification of kidney function in the elderly is difficult, both overestimating and underestimating the glomerular filtration rate (GFR) being possible with currently available serum creatinine-based calculation formulas.

AGING KIDNEY PROCESS

An accurate description of histological changes in the senile kidney, i.e. changes attributed to advanced age per se, is difficult because the elderly usually accumulate important comorbid burdens with impact on the kidney structure and function: diabetes, hypertension, heart failure, etc. Many of the terms that describe physiological changes in the aged kidney superimpose with terms that describe renal pathological processes: nephrosclerosis, tubulointerstitial sclerosis, glomerulosclerosis, arteriosclerosis, etc.

Macroscopically, starting from the 4th decade of age, the kidneys begin to decrease in size and weight progressively, so that around the 7th decade there is a reduction by about 20-30% of kidney weight compared to the age of 40 years [2]; in the elderly without kidney disease, the decrease in kidney size is symmetrical. Also, with age, the kidney's cortex becomes thinner and rougher, the number and size of benign cysts increases, and the pelvis is enlarged with more fatty infiltration. The scarring is more advanced when associated with aortic and renal atherosclerosis (Figures 1 – 5) [3].

Microscopically, starting with the 5th decade of life, there is a progressive decrease in the total number of nephrons due to sclerosis of all nephron compartments [3]: glomerulosclerosis, tubulointerstitial sclerosis, and arteriosclerosis.

The prevalence of glomerulosclerosis increased from 25% in the 3rd decade of life to 82% in the 8th decade [4], the main cause being arteriosclerosis of the small intrarenal arteries.

Figure 1: 87 years old male: granular surface with increased scarring

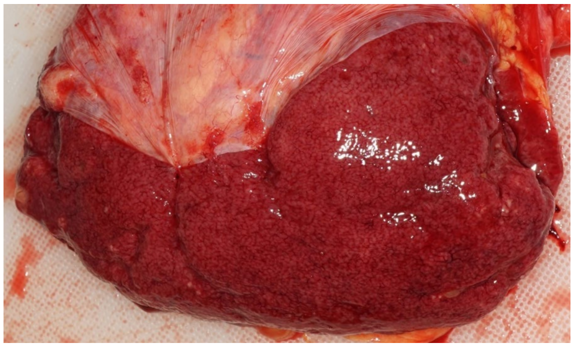

Figure 2: Same case, yellow arrows: small stones, thinning of the cortex

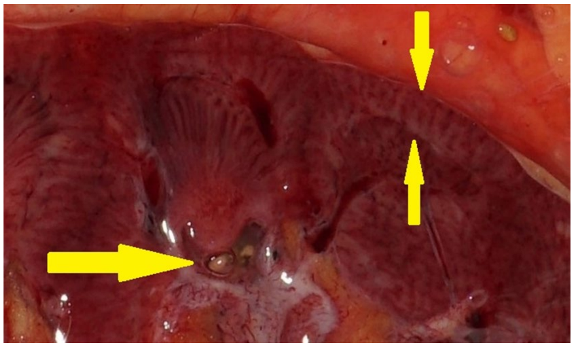

Figure 3: Same case, yellow arrows: glomerulosclerosis (10X HE)

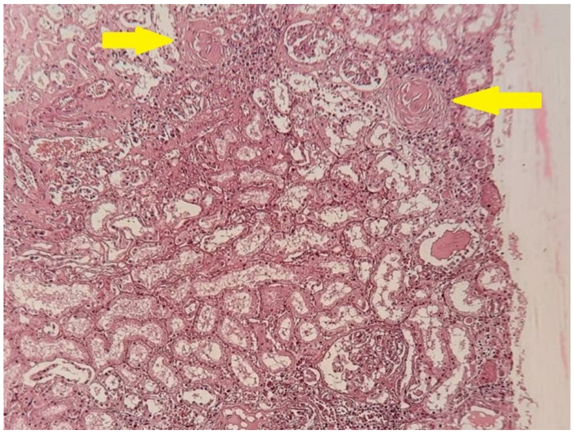

Figure 4: Same case, yellow arrows: arterial wall thickening (10X HE)

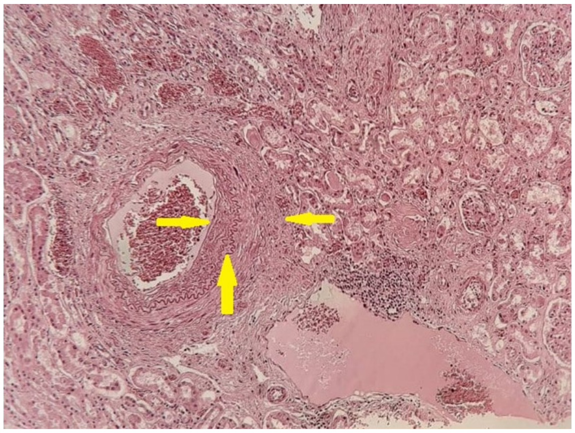

Figure 5: Same case: interstitial sclerosis (10X HE)

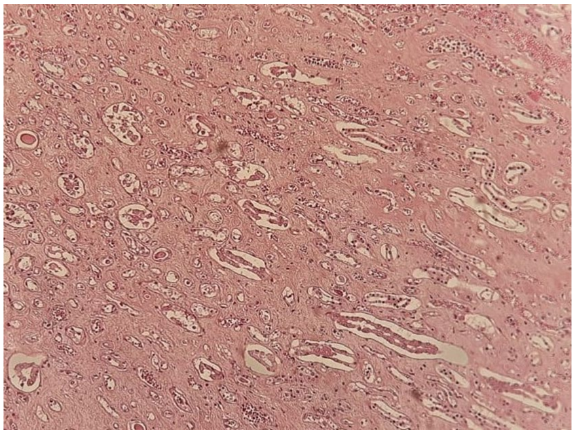

The hallmark of the functional decline of the senile kidney is a progressive decrease in the glomerular filtration rate (GFR) [5]. The decline in GFR begins around the 4th decade of life; between the 8th and 9th decades, the GFR is over 45% lower than at the age of 40 [3,6].

ESTIMATED GLOMERULAR FILTRATION RATE (eGFR) IN ELDERLY

There is no consensus regarding the optimal equation for the estimation of GFR in the elderly. Formulas used in clinical practice in adults – MDRD (Modification of Diet in Renal Disease, CKD-EPI (Chronic Kidney Disease – Epidemiology Collaboration), Cockroft-Gault are all based on serum creatinine levels and they have not been all validated for individuals older than 70 years.

Creatinine-based equations for GFR estimation have several drawbacks in older individuals [7]. Due to age-associated sarcopenia, there is a reduced release of creatinine from the muscles, therefore also a reduced urinary excretion of creatinine [8]. In elderly diabetics, especially in the late-elderly group (75 years or older), it has been noted a more decreased serum creatinine when compared with non-diabetics and this observation was explained by the increased loss of muscle mass promoted by diabetes [9]. Also, the elderly tend to have a reduced intake of proteins and a decreased basal metabolism, therefore, they have supplementary causes for the reduced production of creatinine [10]. Increased metabolism of creatinine by intestinal microorganisms may be an additional cause for reduced levels of serum creatinine, as there are proven age-related alterations of gut microbiota [11]. Formulas using the patient's weight besides serum creatinine give more errors due to increased fat percentage in the organism of the elderly. Several researchers had concluded that both MDRD [12] and CKD-EPI [13] formulas tend to overestimate GFR in the elderly, while Cockroft Gault's [14] formula underestimates it [15,16].

Serum creatinine alone is often used in clinical practice not especially for estimation of GFR, but for monitoring the patient during treatment with a potential nephrotoxic agent (aminoglycosides for example) or a potential ischemic renal insult (cardiac surgery for example). Besides the fact that this conduct is not correct due to the late and modest increase of serum creatinine level compared to the moment and degree of kidney insult, in the elderly, it is a source of supplementary severe misjudgments. The elderly have often lower basal serum creatinine and during an injury renal process, an increase of serum creatinine remains in the range of the normal values of the laboratory and this result may be misinterpreted as a stable state, i.e. no iatrogenic. Moreover, the creatinine increase may be blunted by intensive hydration of the patient applied to minimize the kidney insult.

Formulas based on both serum creatinine and serum cystatin C have been proposed to overcome the disadvantages of formulas based only on creatinine values [17]. Nevertheless, serum cystatin C is influenced not only by kidney function, but also by several diseases often present in the elderly, such as atherosclerosis, inflammatory estates, or obesity [18,19].

Several alternative equations have been developed for older individuals. The HUGE formula (Hematocrit Urea GEnder) was developed in 2011 by a group of researchers from Spain to differentiate patients without CKD from those with CKD [20]; this formula was validated in some studies [21,22].

L = 2.505458 - (0.264418 x hematocrit) + (0.111800 x blood urea); 1.383960 is added for the male patient. For L <0, CKD is excluded; for L> 0, it is classified as CKD.

In 2012, the Berlin Initiative Study (BIS) introduced two new formulas based on serum creatinine and serum creatinine plus serum cystatin C, respectively, for estimating GFR in people over 70 years of age [23].

BIS 1: eGFR = 3736 x serum creatinine-0.87 x age-0.95; in women, the result is multiplied by 0.82.

BIS 2: eGFR = 767 x cystatin C-0.61 x serum creatinine-0.40 x age-0.57; in women, the result is multiplied by 0.87.

Although these formulas have been validated in some studies, there are no large trials to conclude their superior performance, therefore meanwhile guidelines recommend using the same equation as in the general adult population.

NORMAL KIDNEY AGING VERSUS CKD IN ELDERLY

Reported data on CKD prevalence in the elderly is impressive. A highly cited source in the literature is a meta-analysis performed by Hills and collab. which comprises more than 100 reports from all continents; according to this meta-analysis, the prevalence of CKD in all stages in the general population is 13.4% (11,7-15.1%), but increases to 27.6% (range 26.7-28.5%) in the 6th decade and 34.3% (31.9-36.7%) in the 7th decade of life. The same source also revealed increased CKD stage 3-5 in the elderly: from 10.6% in the general population (9.2-12.2%) to 11.3% (8.1-14.5%) in the 6th decade and respectively to 27.9% (16.4-39.3%) in the 7th decade [24]. Nevertheless, a large proportion of the geriatric population meets the KDIGO criteria for CKD even without markers of renal impairment [25,26]. Regardless of the formulas utilized to estimate GFR, an important question needs to get answered in the face of an older patient with abnormal GFR and no markers of kidney disease. Is it CKD without markers of kidney disease or is it normal kidney aging? Several reasons require a response to this question. Establishing a diagnosis of CKD imposes close monitoring of the patient and adequate preparation for conservative or dialysis treatment. Most of the patients aged >65 years have estimated GFR between 45-60 mL/min/1.73m^2; older patients with estimated GFR between 45-60 mL/min/1.73m^2 have, in comparison with younger adults, decreased risk to progress to end-stage renal disease (ESRD), but increased risk to die from other diseases until they reach ESRD [27,28]. Close nephrological monitoring of all these patients would be a significant burden for physicians, and also for the health systems. On the other hand, CKD, even oligosymptomatic, is associated from early stages with increased risk for cardiovascular events and cardiovascular mortality; specific complications of CKD, such as acidosis or increased parathormone (PTH) have early onset and need to be controlled.

There are several subtle clues allowing the differentiation between the physiologic decrease of GFR and CKD (Table 1).

Serum urea and creatinine increase late in the course of CKD in all patients, but especially in elderly patients. Low serum creatinine levels are observed due to decreased basal metabolism, reduced protein intake, and sarcopenia [3], therefore CKD may be present with normal values of serum creatinine in the elderly. However, the aging kidney excretes increased amounts of urea, due to the reduced density of urea channels in the collecting tubes [29]; a normal serum urea level is associated with normal aging [15].

Table 1: CKD versus normal kidney aging

	CKD	***Aging kidney***
Nitrogen waste products in the blood	Increased	Normal
Albuminuria	Present	Absent
Anemia	Present (erythropoietin deficiency)	May be present (nutritional anemia)
Acid-base balance	Metabolic acidosis	Normal
Ca-P metabolism	Hypocalcemia decreased active vitamin D, increased PTH	Possible hypocalcemia, normal PTH, normal active vitamin D

No anemia should be present as in healthy older populations erythropoietin (EPO) production is normal or even increased secondary to increased erythrocyte turnover, increased EPO resistance, or as a response to occult digestive blood losses [30,31]. Nevertheless, in clinical practice, the elderly have often nutritional mild/moderate anemia that may be misinterpreted as CKD-associated anemia. Reduced secretion of EPO in CKD is associated with normocytic and normochromic anemia, while nutritional anemia is often hypochromic and microcytic [32], but they may coexist.

No abnormalities of mineral metabolism are present in healthy older individuals. Renal tubular excretion of calcium, magnesium, and phosphorus is not altered in healthy elderly [5,33]. The elderly are prone to hypomagnesemia, but this seems to be mainly due to reduced dietary intake, decreased intestinal absorption of magnesium, and/or laxative abuse [5]. Although the elderly present more often with mild hypocalcemia, it occurs mainly secondary to native vitamin D deficiency through reduced sun exposure or decreased skin synthesis of vitamin D [34]. In contrast with CKD, there is no deficiency of active vitamin D, nor an increased synthesis of parathormone in healthy elderly.

Under basal conditions, the kidneys of the elderly have a normal capacity for the excretion of acids and the acid-base balance does not undergo significant changes even with a normal- or hyper-protein diet [35]. However, the renal reserve of the elderly is reduced and a rapidly installed high acid load may be difficult to be compensated by the senile kidney; the elderly are highly vulnerable to the side effects of acute metabolic acidosis (uncontrolled diabetes, sepsis, acute kidney injury).

On the other hand, the presence of albuminuria is a strong argument for CKD even if the patient has other comorbidities that may explain this finding (systemic atherosclerosis, diabetes, cardiac failure). Albuminuria is associated with an increased risk of progression of CKD [36], therefore applying antiproteinuric measures might have the same benefits in the elderly as in younger adults, i.e., attenuating the progression of CKD and reducing cardiovascular events [37]. Nevertheless, overzealous administration of RAAS inhibitors in the elderly is associated with an increased risk of side effects (hypotension, hyperkaliemia, acute kidney injury) in the presence of reduced GFR and systemic atherosclerosis or other comorbidities; another reason why these drugs are no longer needed in elderly without proteinuria is the fact that they become useless, not having time to install their renoprotective effect over time [38,39]. The elderly are prone to hyperkaliemia even in the absence of reduced GFR due to the low sensitivity of distal tubules to aldosterone [31,40].

Taking into account that the elderly have a higher risk of death due to various complications than to progress to ESRD, there is a need to assess individual risk for these outcomes to analyze treatment options and make early plans for conservative treatment (diet, prevention, and control of uremic syndrome with medication) or renal replacement therapy. CKD has an extremely heterogeneous presentation in the elderly; between an independent full-functioning person without cognitive impairment and without major comorbidities at one pole to a frail, immobilized in-bed individual with severe cognitive dysfunction, multiple disabling comorbidities and total dependence for medical care at the other pole, there are numerous clinical pictures. One such equation was proposed by Tangri et al in 2011 who developed the Kidney Failure Risk Equation (KFRE) using variables like age, sex, estimated GFR, albuminuria, serum calcium, serum phosphate, serum bicarbonate, and serum albumin to predict progression toward ESRD after 1, 3 and 5 years respectively for patients with CKD stages 3 to 5 [41]; a variant using only 4 variables (age, sex, estimated GFR and albuminuria) may be used, but the results offer less accuracy [41]. This model has not been designed especially for older individuals, but it has been validated both for patients < 65 years and those above this age and for various races [42,43]. Calculation of this score is available on the internet at http://www.qxmd.com/Kidney-Failure-Risk-Equation. KFRE is recommended by European Renal Best Practice Group to be used in elderly with an estimated GFR < 45 mL/min/1.73 m^2 to assess progress toward ESRD [44]. Nevertheless, a lot of old individuals are placed in the range of GFR between 45-60mL/min/1.73 m^2 and have no markers of kidney disease (albuminuria) [45]; there are no available validated prediction models for this situation and members of European Renal Best Practice Group opine for the urgent need of such prediction models.

Regarding the prediction of death, in the literature there are numerous scores specially designated for the old population and most of them also include, besides demographic variables (age, gender) and comorbidities (heart failure, diabetes, active neoplasia, anemia, history of stroke, chronic obstructive pulmonary disease, etc.), a marker of kidney dysfunction such as estimated GFR or urinary albumin/creatinine ratio [46-49]. These models estimate the risk of death at periods ranging from 3 months to 5 years. The European Good Practice Guideline recommends the use of the Bansal score in current practice for assessing the risk of mortality of non-fragile, un-institutionalized elderly people with CKD >stage 3b [44,47]; this score uses 9 variables - age, sex, GERD, urinary albumin/ creatinine ratio, smoking, diabetes, heart failure, history of stroke; according to this predictive model, the 5-year mortality varies between 3.8% for individuals with lower scores to 83.6% for individuals with all 9 items reached. Nevertheless, again, none of these models took into analysis the particular situation of individuals with normal kidney aging, i.e. those patients without markers of kidney damage and GFR between 45-60 mL/min/1.73m^2. We found in the literature just one publication, that of Van Pottelbergh and collab. who analyzed mortality of very old (>85 years) individuals with GFR> 60 mL/min versus those with GFR between 45-60 mL/min [50]. According to the authors of this paper, the combination of the baseline estimated GFR and the estimated GFR slope over 3 years can be used to assess the risk of death; in the subgroup of patients having estimated baseline GFR between 45-60 mL/min only those with a GFR decrease ≥ 5 mL/min/year had an increased risk of death, while among patients with baseline GFR > 60 mL/min, a decrease of ≥ 3mL/min/year was associated with increased risk of death. The same authors explained that these changes are a reflection of cardiovascular damage. Also, the authors share the opinion of a lot of others those older adults with GFR between 45-60 mL/min should not be classified as moderate stage 3 CKD.

CONCLUSIONS

Aging associates the functional decline of all tissues and organs secondary to degenerative structural changes. Normal kidney aging is a complex process that is difficult to be differentiated in clinical practice from chronic kidney disease with contemporary available criteria; both share the reduced glomerular filtration rate as the main feature. Nevertheless, it is important to make this differentiation.

Establishing a diagnosis of CKD imposes periodic nephrology consultation for monitoring the progression of the disease, treatment of complications, early planning of conservative or dialysis treatment, and also adjustment of treatment of multiple comorbidities of the elderly. CKD has multiple complications and requires often interdisciplinary care: cardiologists, neurologists, psychiatrists, nutritionists, etc. On the other hand, proving that reduced GFR is only a sign of normal aging and that there are no markers of kidney damage allows gerontologists to provide holistic care for slowing the aging process and minimizing the incidence of high-risk diseases in the elderly.

Thus, misclassifying an elderly person as a patient with CKD involves an unnecessary psychological burden for the patient and his family, as well as unnecessary medical care and increased financial expenses.

Conflicts of interest and sources of funding
The authors declare no conflict of interest.

Abstract: *Introduction: Gastric mesenchymal tumors are a pathology that is increasing in incidence in recent years but the treatment is not yet standardized. The laparoscopic approach to these lesions is a modern option, with the patient benefiting from the advantages of minimally invasive surgery. Methods: We included in the study 4 patients operated laparoscopically for suspicion of gastric GISTs between Mars 2019 and May 2022. From a prospectively kept database, we extracted the following characteristics: age, sex, length of postoperative hospital admission, operation time, tumor location, tumor size, histopathological assessment of resection margins, intraoperative blood loss, and incidence of postoperative complications. Results: Average tumor size was 4.3 cm, ranging from 4 to 6 cm. Laparoscopic wedge resection was possible in all cases. There was no conversion, no episode of tumor rupture or spillage, and no major intraoperative complications. Histology confirmed a GIST in 3 of 4 cases. In one case histological workup showed gastric schwannoma. Conclusion: Laparoscopic wedge resection for gastric stromal tumors, even larger than 5 cm, appears to be safe and feasible in selected patients, with acceptable operative time and oncological outcome after an intermediate follow-up. More important than the size of tumors that are approached laparoscopically is their location and the possibility of a stenosis-free resection.*

Keywords: *laparoscopic wedge resection, Gastrointestinal Stromal Tumors (GIST), gastric mesenchymal tumors, Schwannoma*

INTRODUCTION

Gastric tumors can be divided into epithelial and subepithelial tumors based on their origin. 90% of gastric tumors including adenoma and adenocarcinoma originate from epithelium [1]. Various tumors occur as subepithelial lesions, including mainly gastrointestinal stromal tumors (GISTs) and leiomyomas, less often neuroendocrine tumors, schwannoma, lymphangioma [1], lipomas, granular cell tumors, and ectopic pancreatic tissue [2].

Epidemiology

GIST is the most common mesenchymal tumor of the gastrointestinal tract [3], with an incidence of about 1-1.5/100,000 persons/year [4,5]. Few studies have indicated that the incidence of GIST is greater in patients undergoing bariatric surgery (0.6%- 0.8%) than in the general population [6]. Increased body mass index has been linked with a higher risk for several types of cancer. Another possible hypothesis for the high incidence found in these studies is that many small, asymptomatic GISTs are underdiagnosed in the general population [7,8].

Gastric stromal tumors account for about 60-70% of all GISTs [4,9,10]. The term is relatively recent, it was first used in 1983, to reclassify a subset of tumors previously identified as leiomyomas or leiomyosarcomas [11,12]. Typically, GISTs are solitary tumors identified slightly more often in males than females of middle to advanced age (between 40 and 80 years) [6,7]; however, the estimated mean age at diagnosis is in the sixth decade of life [13].

Histological Findings

GIST originates from the interstitial cells of Cajal, the pacemakers of the gastrointestinal tract [14], or their stem cell precursors [15]. Their defining characteristic is a gain-of-function mutation in genes coding for the KIT tyrosine kinase receptor, which is considered the driving force of cell proliferation in this tumor [16].

Diagnosis of GIST was based on microscopic analysis, including immunohistochemistry with a panel of antibodies: Cluster of

Differentiation-117 (CD117), Cluster of Differentiation-34 (CD34) and Discovered on GIST-1 (DOG1), S-100 protein, desmin, and smooth muscle actin [17,18].

Natural Evolution

GISTs are not classified as either benign or malignant but are rather stratified by their clinical risk of malignancy: very low, low, intermediate, or high [13]. The malignant potential depends on tumor cell mitosis, tumor size, tumor location [17, 19], and tumor rupture [5]. Approximately 10% to 30% of GISTs have a malignant clinical course [13] because they can metastasize hematogenously to the solid viscera, including the liver, small bowel, and lungs [14]. In these conditions, the only absolute signs of malignancy are metastasis or invasion into adjacent organs [16].

Biologically, tumors grow locally within the stomach wall (intra- or extraluminal expansion) and can also spread along the smooth muscle planes within the stomach or can rupture into the peritoneal cavity causing sarcomatosis [10].

Clinical presentation and incidental GIST

The most common symptoms of GISTs are gastrointestinal bleeding, including acute melena and hematemesis [13] with subsequent anemia, weakness, and abdominal pain [18], distension, and discomfort due to a tumor-induced mass effect or metastasizing tumors [16]. Tumor hemorrhage commonly occurs when large tumors develop an ischemic, punctate ulcer. Usually, the bleeding can be controlled using endoscopic sclerotherapy or electrosurgical coagulation techniques [10].

15% to 30% of patients with GISTs are asymptomatic and are diagnosed incidentally, during examinations for other reasons, during surgery for other diseases [6,15], or during postmortem autopsy [13]. In these asymptomatic patients, tumors grow insidiously and can sometimes reach large sizes.

Diagnostic Process

With the popularity of screening endoscopy, increasing gastric submucosal tumors are incidentally detected [20]. The main endoscopic finding of GISTs is common to all subepithelial lesions: a nonspecific smooth bulge covered with normal mucosa [13].

Diagnostic workup can be challenging and consists of endoscopy, ultrasonography, computed tomography, magnetic resonance imaging, and endoscopic ultrasonography with fine needle aspiration [13]. However, a biopsy specimen is often negative [15].

Treatment

The treatment strategy for immunohistologically confirmed GISTs is as follows: surgical resection is the first choice for resectable GISTs without metastasis and administration of imatinib is the primary approach for unresectable, metastatic, or recurrent GISTs [13].

Medical Treatment

In 2000, imatinib (first-line tyrosine kinase inhibitor) was first used to treat patients with advanced GIST, achieving unprecedented treatment responses in a tumor type that – when metastatic – was previously rapidly lethal [12]. The drug was approved for use as adjuvant treatment after the surgical removal of high-risk GISTs in 2012 when it is administered in an attempt to reduce the recurrence rate [8]. Sunitinib (second-line tyrosine kinase inhibitor) and Regorafenib (third-line multikinase inhibitor) can be used in advanced cases after treatment failure with Imatinib. However, it is difficult to obtain a permanent cure with tyrosine kinase inhibitors [13].

Surgical Treatment

In contrast to gastric adenocarcinoma, where gastrectomy with wide margins and lymphadenectomy is recommended [10], limited gastric resection is the recommended surgical approach for GIST, because it grows by expansion rather than diffuse infiltration and rarely invades nearby lymph nodes [5, 14,19]. Wide margins and lymph node dissection do not improve survival or decrease recurrence [11].

The surgery aims to achieve a complete resection with no tumor residue [17,21]. Moreover, strict avoidance of intraoperative tumor rupture is crucial for preventing tumor relapse [16].

Traditionally gastric GISTs resection was done with open surgery, but, more recently, less invasive methods have been reported [18]. The first description of laparoscopic resection of a GIST was in 1992 when Lukaszczyk discovered and resected an incidental gastric mass during a laparoscopic cholecystectomy [11]. The choice of the laparoscopic or open method was made by the surgeon based on his evaluation and the patient's consent [19].

As experience accumulated, initially tumors up to 2 cm [18, 22], then between 2 and 5 cm [4], and more recently between 5 and 10 cm were approached laparoscopically [21]. Prerequisites for the laparoscopic approach were the absence of metastases and the presence of a well-defined tumor on CT scanning without the involvement of adjacent organs, the esophagogastric junction, or the pylorus of the stomach [18, 19]. However, wedge resection sometimes involves inadvertent resection of additional gastric tissue, which can produce gastric deformation. Anatomic gastrectomy (subtotal or total gastrectomy) is reserved for large tumors that involve a significant portion of the stomach [10].

METHODS

After obtaining our institutional review board approval, we retrospectively reviewed the medical records of our patients operated laparoscopically for gastric GISTs between March 2019 and May 2022.

Study Population and Data Analysis

We extracted the following characteristics: age, sex, length of postoperative hospital admission duration, operation time, tumor location, tumor size, histopathological assessment of resection margins, intraoperative blood loss, and incidence of postoperative complications (surgical and non-surgical). Patients were eligible for laparoscopic surgery if preoperative staging (endoscopy and CT scan) showed a localized, non-metastatic extra mucosal gastric lesion (Figures 1, 2). Tumors were required to be of a diameter and in a position that suggested resectability through segmental or wedge resection. Preoperative histological confirmation of the diagnosis was not a prerequisite for inclusion.

Figure 1: Subepithelial gastric tumor with a clot on the surface (Case 4)

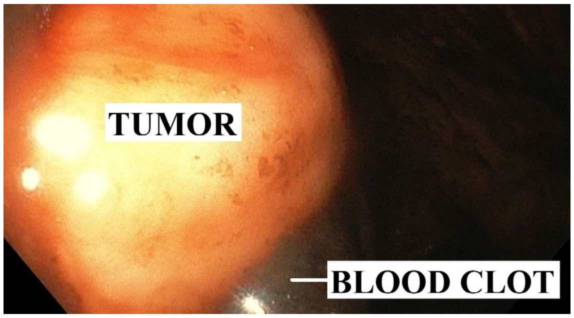

Figure 2: CT scan image (Case 1)

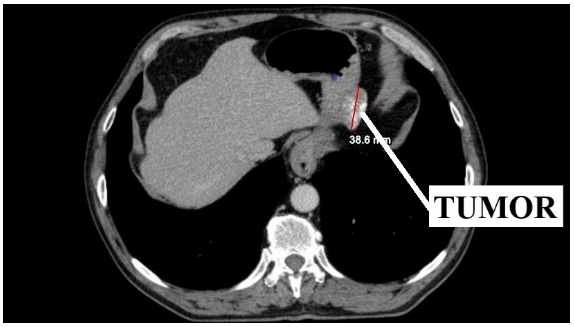
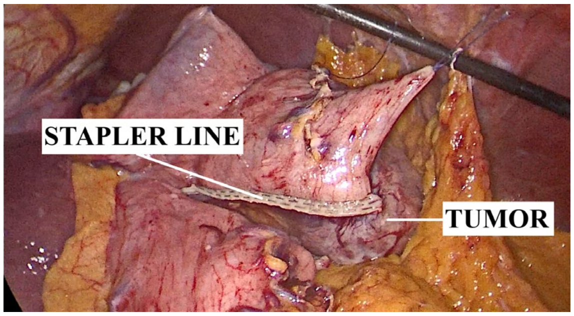


Surgical Resection Procedures

All patients were treated by laparoscopy while under general anesthesia. The patient was placed supine in the anti-Trendelenburg position and the surgeon stood between the legs. Using a Veress needle, the pneumoperitoneum was achieved with CO_2 at 12 mmHg pressure. The first trocar was placed on the median line, about 15 cm from the xiphoid process. Under visual control, another 3 or 4 work trocars were introduced. After checking all the abdominal cavities for metastases, the lesion was identified through visualization and palpation. In the case of tumor location at the posterior wall of the stomach, the gastrocolic ligament was dissected and the stomach was inverted to display the lesion. The tumor-bearing gastric segment was resected with several 60 mm endoscopic linear staplers (EndoGIA) (Figure 3). To avoid stenosis of the stomach during wedge resection, a calibration tube (36 Fr) was inserted by the anesthesiologist. Special care has to be taken to prevent peritoneal seeding and the possibility of capsular rupture during manipulation.

Figure 3: Intraoperative image, after the first EndoGIA cartridge is placed (Case 4)



The resection specimen was placed into a plastic retrieval bag and removed through one of the extended port incisions. Stapler lines were visually controlled and, if deemed necessary by the surgeon, their integrity was assessed through the application of methylene blue solution via a nasogastric tube (blue test). At the end of the operation, a drain tube was placed in the vicinity of the staple line.

Pathological evaluation

The specimens were fixed in 10% formalin solution and sent for pathological evaluation. The characteristics of gross specimens were described, including tumor size, gross appearance, ulceration (Figures 4, 5). After sectioning, hematoxylin and eosin staining was regularly performed followed by immunohistochemical staining.

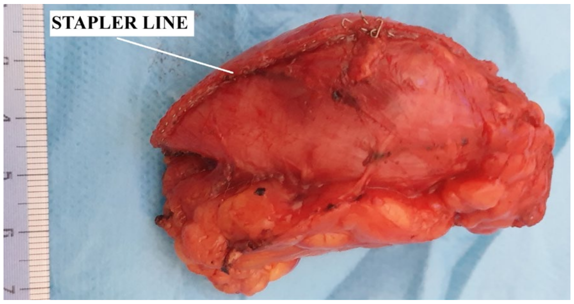

Figure 5: The specimen, with the suture line open (for inspection of the resection margins) (Case 2)

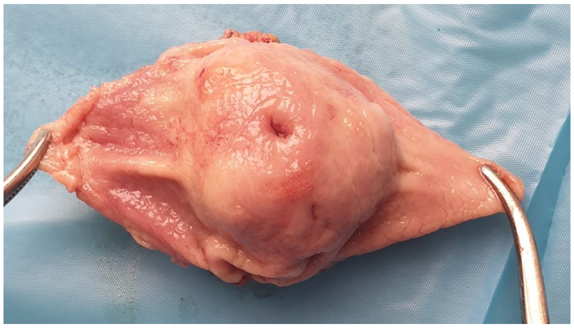

Follow up

Patients with immunohistochemically confirmed GIST were referred to the oncology department for therapeutic management

RESULTS

Four patients were planned for a laparoscopic wedge resection of a suspected gastric GIST. The presented cases were 3 females and 1 male with a median age of 70.25 years (between 64 and 74 years).

The reasons for admission to Gastroenterology Department were abdominal pain (3 patients), weakness (2 patients), anemia (2 patients), and gastrointestinal bleeding (1 patient).

All patients were investigated by endoscopy and CT scan. The average tumor size was 4.3 cm, ranging from 4 to 6 cm. The main patient data are summarized in Table 1.

The average operation time was 77.5 min, ranging from 60 to 100 min. Resection was performed using between 2 and 3 cartridges. Because the operated lesions were large, there was no need for intraoperative endoscopy to identify the tumor's location. Laparoscopic wedge resection was possible in all cases. There was no conversion, no episode of tumor rupture or spillage, and no major intraoperative complications. Intraoperative blood loss was below 50 mL in all patients and no patient required blood transfusions. The surgical margin of all tumors was confirmed using the extracted specimen.

All tumors were resected with macroscopic and pathologically negative margins. Histology confirmed a GIST in 3 of 4 cases. In one case histological workup showed gastric schwannoma.

The median postoperative hospital stay was 5.5 days, ranging from 5 to 7 days. Hospitalization was 5 days for 3 of the patients and 7 days for one patient who had a postoperative complication. One patient (with a tumor size of 3.5 cm) experienced a postoperative hemorrhage (grade II complication after Clavien-Dindo classification). This was treated conservatively with proton pump inhibitors. We had not identified any other postoperative complication.

Table 1: Patients data

Case number	1	2	3	4
Age	74	71	64	72
Sex	Male	Female	Female	Female
Histology	GIST	GIST	Schwannoma	GIST
Location	Fundus/ Greater curvature/ Anterior wall	Body of the stomach/ Lesser curvature/ Posterior wall	Body of the stomach/ Lesser curvature/ Anterior wall	Body of the stomach/ Greater curvature/ Posterior wall
Morphology	Pediculated	Extraluminal	Extraluminal	Extraluminal
Operation time	70 minutes	100 minutes	80 minutes	60 minutes
Number of cartridges	2	2	2	3
Dimension of resection	6x5 cm	7x6 cm	6.2x5 cm	9x8 cm
Tumor size	4 cm	3.5 cm	4 cm	6 cm
Tumor staging	pT_2	pT_2	-	pT_3
Risk of malignancy	Very low	Low	-	High

In the same period, outside this study, in our department, a patient with a massive tumor (18.8/18/13 cm) was treated by open subtotal gastrectomy.

All patients were referred for oncological consultation, but only 2 patients did it. Due to the favorable histopathological exam, absence of distant metastases at the time of diagnosis and on the subsequent follow-up (annually CT), and absence of local recurrence on follow-up endoscopy (6 months postoperatively, then annually), the patients did not indicate adjuvant chemotherapy.

All patients were alive at the end of this study and in good health.

DISCUSSION

Open surgery was the traditional and most widely used treatment for gastric stromal tumors. When possible, the endoscopic or laparoscopic approach is safe and leads to non-inferior outcomes compared to the open approach [21].

Although our experience is limited, we can state that the cases we have treated by laparoscopic wedge resection and presented have progressed favorably, benefiting from the well-known advantages of laparoscopic surgery. Among the other variants of the laparoscopic approach found in the literature, we list the following: non-anatomic full-thickness removal of a disk of tissue with the closure of the resulting gastrotomy, anatomic partial gastrectomy with reconstruction, and transgastric resection [11].

The choice of laparoscopic approach must take into account both the size of the tumor and its location. Visible lesions on the anterior gastric wall are most suitable for wedge resection, consisting of lifting the lesion and performing a wedge resection by application of one or more endoscopic linear stapler devices. But selected cases can be approached laparoscopically even if they are not located on the anterior wall. On the other hand, patients with lesions near cardia or pyloric antrum are not proper candidates for wedge resection due to potential stenosis. Therefore, limited gastrectomy is usually used, but alterations of anatomic structures may lead to functional disturbance and impaired quality of life [20]. In our patients, we did not find any early postoperative stenosis. Concerning long-term functional results, we were not confronted with symptoms or endoscopic signs of reflux or stenosis during postoperative follow-up.

As experience with minimally invasive surgery has increased over the past decade, laparoscopic surgery for gastrointestinal malignancies has become increasingly common [5]. As in other laparoscopic procedures, the existence of a learning curve must be assumed. However, due to the experience gained by the two senior surgeon authors in oncological surgery and bariatric surgery (sleeve gastrectomy), the surgical interventions for the presented cases were carried out in good conditions. Being tumors with malignant potential, all measures must be taken to prevent tumor injury.

In our small case series, 1 out of 4 tumors preoperatively suspected to be a GIST were histologically diagnosed as gastric schwannoma. Schwannomas are benign, slow-growing, encapsulated nerve-sheath tumors arising from Schwann cells, meant for the myelin sheath formation in the peripheral nervous system. Gastric schwannoma is a rare gastric mesenchymal tumor, which accounts for 6.3% of the gastric mesenchymal tumor, 4% of all benign gastric tumors, and 0.2% of all gastric tumors. Being different from GISTs, they are considered as being benign, slowly growing, and with excellent prognosis [20]. Retrospectively, in this case, surgical resection would have not been required for oncological reasons. We also found this situation in the literature studied [14,16,23], and it's explainable because we didn't have a preoperative histological diagnosis. On the other hand, it is considered that all localized resectable gastric stromal tumors with a diameter of 2 cm or more need resection [2,4]. Preoperative histological diagnosis of submucosal gastric lesions is however not always feasible through endoscopic biopsy [16]. With the benign and mostly asymptomatic nature of gastric schwannomas, endoscopic follow-up is also an alternative method. But it is not widely adopted due to the lack of a standardized surveillance strategy, the risk and cost-effectiveness of repeated endoscopic procedures, and patients’ stress and compliance [20].

CONCLUSIONS

In conclusion, laparoscopic wedge resection for gastric GIST, even larger than 5 cm, appears to be safe and feasible in selected patients, with acceptable operative time and oncological outcome after an intermediate follow-up.

More important than the size of tumors that are approached laparoscopically is their location and the possibility of a stenosis-free resection.

Abstract: *Psoriasis is a chronic inflammatory skin condition with genetic determinism characterized by the presence of well-defined, erythematous plaques, covered by white, pearly, stratified scales, located on the extension areas, the skin of the scalp, intertriginous regions. The origin of psoriasis is multifactorial, involving hereditary and environmental pathogenic mechanisms. It is triggered by various risk factors involving a variety of processes, such as inflammation, antigen presentation, cell signaling, and transcriptional regulation.*

Keywords: *psoriasis vulgaris, inflammation, immune system*

OVERVIEW

Definition

To have a starting point and be able to go deeper into a subject, as in any field, and in the case of diseases, we must first know the definition. A definition must be as complete as possible, to create an overall picture of the disease.

Psoriasis is a chronic inflammatory skin condition [1], proliferative [2], with genetic determinism [3], characterized from a clinical point of view by the presence of well-defined, erythematous plaques [4], covered by white, pearly, stratified scales [5], located on the extension areas and in the skin of the scalp.

If it was initially considered a benign dermatological condition, psoriasis is now accompanied by multiple comorbidities, being considered a multisystemic inflammatory disease [6]. In addition to the impact it has from an aesthetic point of view, psoriasis also significantly influences patients' quality of life [7].

A recent study estimated that the psychological impact in patients with psoriasis is severe, between 10-62% [8]. Among the most common symptoms are: low self-esteem, sexual dysfunction, suicidal ideation, which occurs in up to 10% of patients with psoriasis, decreased professional opportunities, stress – which can trigger psoriasis flare-ups, depression [8].

Incidence

Worldwide, the prevalence of psoriasis is between 0.5%-11.4% in adults [9], and this increases with increasing distance from the Equator [10]. Recent studies have shown that in Australia the prevalence of psoriasis in adults is between 2.3% - 6.6% and 1.3% - 2.2% in the United Kingdom [11].

While most cases of psoriasis often appear before age 35, it can develop at any age [12], and men and women are equally affected [13].

ETIOPATHOGENESIS

The cause of psoriasis is not known, but it was found to be a condition with multifactorial determinism [14], which to manifest itself clinically requires the presence of genetic and environmental factors [12].

About 40% of people with psoriasis or psoriatic arthritis have a family member with psoriasis [15].

The major susceptibility locus in psoriasis: PSORS 1 (6p21.3) within the MHC gene complex is present in approximately 30% of patients with psoriasis [15].

In patients with genetic predisposition, environmental factors can have a triggering or aggravating effect on the disease, and among the most frequently involved environmental factors are: trauma, infections, endocrine factors, certain drugs, alcohol, smoking, and obesity [16].

Pathogenic hypotheses

As mentioned, the origin of psoriasis is multifactorial, involving hereditary and environmental pathogenic mechanisms [17]. At the epidermal level, there is hyperproliferation and abnormal differentiation of keratinocytes, as well as activation of the skin's immune system [18].

Human histocompatibility system (HLA)

The major histocompatibility complex (MHC) also known as human leukocyte antigen (HLA) is one of the most genetically diverse regions in the genomes of different species [18].

More than 500 associations have been identified in the HLA region for approximately 200 phenotypes, including immune deficiencies, autoimmune diseases, susceptibility to infections, malignancies, and psychiatric conditions (Welter et al. 2014) [18].

The function of gene families at the level of MHC in the occurrence of autoimmune diseases has been the subject of research for decades [19].

Psoriasis is characterized by epidermal hyperproliferation and dermal inflammation [20], mediated by T cells [21]. Efforts to study genetics in psoriasis continue, with nine susceptibility loci (PSORS1-9) being identified [22]. The PSORS1 locus is considered the genetic determinant of psoriasis [23].

From the human genome, MHC is one of the most studied regions [24], with multiple genetic variants at this level that have contributed to the emergence of diseases such as psoriasis, Crohn's disease, systemic lupus erythematosus, rheumatoid arthritis [25].

MHC is located on chromosome 6p21.3 and is divided into 3 regions: the centromeric region (MHC III) and the telomeric regions (MHC I and II) [26].

The genome-wide association study (GWAS) demonstrated that at the MHC level there are SNPs associated with the occurrence of psoriasis [27].

The major locus involved in the development of psoriasis – PSORS 1 – located at the MHC level is probably associated with non-MHC loci with common alleles [28], which determines the genetic heterogeneity of psoriasis [29].

Certain gene combinations increase the risk of psoriasis, while others decrease it. Patients with psoriasis have been observed to have a higher prevalence of HLA-Cw6, HLA-B13, HLA-Bw17, and HLA-B37 antigens [27].

Major susceptibility locus (PSORS1)

While the major susceptibility locus is PSORS1, other susceptibility loci seem to also play important roles: PSORS2 (17q24-q25) [26].

Molecular studies revealed the following "candidate" genes for psoriasis:
- Gene S located on HLA-Cw6 (expresses the duration of keratinocyte differentiation) [26].
- Genes from the differentiation complex PSORS4 (1q21-q22) - encoding molecules involved in the terminal differentiation of keratinocytes [28].
- PSORS 5 (predisposition in Swedish families) [26].
- PSORS 8 (susceptibility to Crohn's disease and psoriatic arthritis [27].
- PSORS 9 (predisposition in Chinese families) [28].

The immune system

Psoriasis is an incurable autoimmune disease with genetic determinism, mediated by T lymphocytes…

Immunity includes all the physiological mechanisms that allow the body to recognize and eliminate a "non-self" antigen [30]. To be effective, the immune system must differentiate between "self" – cells, proteins that belong to the body and "non-self" – pathogens or substances foreign to the body [31].

There are two types of immune system response:
- Innate immunity = non-specific (which generates an immediate response)
- Acquired immunity = specific

Innate immunity includes two main lines of defense:
A) Physical barriers: skin, mucous membranes, cilia.
B) Chemical barriers: saliva, mucus, acid environment in the stomach, sweat, lysozyme.

Acquired immunity involves:
- The inflammatory response
- The complement system
- Cellular components

The innate immune response is naturally present in humans and is not pathogen-specific. The acquired immune response triggers a specific cell-mediated response through T lymphocytes, which secrete cytokines, and humoral through B lymphocytes, which secrete antibodies [31].

Psoriasis, the chronic inflammatory skin disease [1], is characterized by abnormal innate and acquired immunity [30], which is associated with aberrant differentiation and hyperproliferation of keratinocytes [31].

Pathogenic hypotheses

Psoriasis is a complex genetic disorder that is triggered by various risk factors involving a variety of processes, such as inflammation, antigen presentation, cell signaling, and transcriptional regulation [33]. Persistent inflammation in psoriasis causes uncontrolled differentiation and proliferation of keratinocytes [34]. It is considered that both keratinocytes and other cell types are involved in the appearance of the psoriatic plaque, from whose interaction in the superficial epidermal layers the persistent inflammation results [35].

From a histological point of view, the changes that appear in psoriasiform skin are acanthosis, parakeratosis, and hyperkeratosis [36].

In the most recent meta-analysis performed on genome-wide association studies, 15 new PSORS-type loci were identified, bringing their number to 36 [37]. Among the loci identified are several that encode the NFkB signal transduction cascade, such as REL, NFKBIA, TRAF6, CARD14, and ILF3 [37].

Studies at the level of the entire genome emphasize the complexity of gene changes involved in the occurrence of psoriasis [38].

In several reports, the role of the nervous system in the pathogenesis of psoriasis was emphasized, and its involvement was based on the symmetrical distribution of lesions on the body and the interaction of sensitive peripheral nerves with immunomodulatory networks [39].

Cases have also been reported in which surgical denervation of psoriasis lesions or local anesthesia would decrease local inflammation [39].

Emotional stress, as well, has been reported as being involved in the onset of psoriasis or its exacerbation [40].

Over time, research has shown that the immune system has a key role in the development of psoriasis [41].

Classically, psoriasis is a systemic inflammatory disease [1], controlled by T cells [3], and modulated by genetic and environmental factors [2].

The presence of macrophages, lymphocytes, and neutrophils in the skin is a characteristic sign of psoriasis [7]. Therefore, the disruption of the innate and adaptive skin immune response, to which is added the presence of non-immune cells, determines the support of inflammation [9].

THE ACTIVE MOLECULAR ENVIRONMENT IN PSORIASIS

The activity of the immune system does not consist only in its specificity, but also in the elaborated communication network through the cytokines secreted by the activated immune cells [42].

Cytokines are small, soluble proteins that allow the recruitment of other immune cells, such as T lymphocytes or dendritic cells, and are involved in identifying the site of infection [43].

The key groups of cytokines are represented by: IL, interferon (IFN), and tumor necrosis factors (TNF) [42].

IL-1 is produced by macrophages, monocytes and other types of cells, being composed of IL-alpha and IL-beta, with a key role in the inflammatory response [44].

It binds to the specific receptor – IL-1R and its accessory protein (IL-1RAcP) [43], further activating a complex intracellular signaling network [45].

This ultimately leads to the induction of transcription factors, such as NFκB, resulting in inflammatory immune responses [46].

The IL-beta subunit has an important role in psoriasis, inducing the proliferation of T cells, which produce IL-17 and thus maintain the inflammatory processes in psoriasis [47].

Therapies targeting IL-1 have not demonstrated satisfactory results in plaque psoriasis, but satisfactory results have been obtained in generalized pustular psoriasis [45].

IL-23 is a cytokine formed by two subunits, p19 and p40 [48], involved in antifungal and antibacterial defense [49]. It is produced by macrophages and dendritic cells, and the receptor to which it binds consists of IL-23 R and IL-12Rbeta1 [50]. Furthermore, it determines the activation of transcription factors, including STAT-3 [51].

It cannot activate naive T cells alone, because they do not have specific receptors, but it is involved in the pathogenesis of psoriasis through Th 17 cells [52].

The development of anti-IL-23 therapies has shown excellent efficacy in the treatment of psoriasis [51].

Th17 cells, neutrophils, mast cells, Nk cells, and B cells are the source of IL-17 [52], The IL-17 family has 6 members (IL-17A – IL-17F) that bind to specific receptors [53].

In macrophages and fibroblasts, IL-17 induces the expression of pro-inflammatory molecules (IL-1p, IL-6, GM-CSF, TNF-alpha) [52].

Having a pro-inflammatory role, it can cause autoimmunity in the immune system, which has been demonstrated for rheumatoid arthritis, psoriasis, and inflammatory bowel disease [53].

IL-17 is involved in the inflammatory process from metabolic disorders, such as hepatic steatosis and arteriosclerosis [54] so IL-17 antagonists can also intervene in the improvement of comorbidities, not only in the treatment of psoriasis [55].

IL-22 is part of the same family of cytokines as IL-10, and the active form is a monomer that binds to its specific receptor, located at the level of epithelial cells and fibroblasts of various cells [56]. It consists of heterodimeric subunits (IL-22R1 and IL-10R2) [57].

IL-22 is produced by CD4 (Th1, Th17, Th22) and CD8 lymphocytes, innate lymphoid cells, and NK cells [58].

The transcription factor RORγt is essential for IL-22 production because CD4 + cells secrete IL-22 only in the presence of this receptor [59].

The serum level of IL-22 is correlated with the activity of the disease [57] and in the skin with psoriasis lesions, the level of IL-22 is increased [58]. This causes keratinocytes to migrate, preventing their differentiation, and leading to the thickening of the epidermis [59]. Therefore, IL-22 could represent a potential target for the treatment of psoriasis [57].

IL-12 is produced by dendritic cells, macrophages, and neutrophils, being a heterodimer formed by the p35 unit and the p40 unit [62]. Its receptor is mostly found on T cells and N cells [65] and consists of IL-12 Rbeta 1 and IL-12Rbeta2 subunit [63]. The binding of IL-12 to the receptor activates the JAK/STAT pathway [67]. Although IL-12 increases IFN-gamma and TNF-alpha [68] molecules involved in the pathogenesis of psoriasis, an increased level of the p35 subunit was not detected in the skin of patients with psoriasis [69], and targeting the p40 subunit exerted its effects by inhibiting IL-23 [70].

The main sources of interferon-gamma - type 2 interferon (IFN-γ) are CD4+ and CD8+ cells, NK cells, but also antigen-presenting cells and B cells [69]. It is involved in antiviral and antibacterial defense [67]. The IFN-gamma receptor consists of two IFNGR1 chains and two IFNGR2 chains responsible for signal transduction [71], which leads to the activation of the JAK/STAT signaling pathway [72]. The serum level correlates with the activity of the disease, being higher in patients with psoriasis [70]. Greater decreases in serum IFN-gamma are associated with longer periods of disease remission [67], but anti-IFN-gamma therapy has not demonstrated efficacy on psoriasis lesions [70].

The role of TNF alpha in the inflammatory mechanisms of psoriasis

TNF-α is produced by macrophages, monocytes, keratinocytes, and lymphocytes, being a pro-inflammatory cytokine [72], involved in both acute and chronic inflammation [71], with an antibacterial and antitumor role [70].

Receptors for TNF are found in all nucleated cells [69] and are formed by two main isoforms: TNFR1 and TNFR [73].

TNF alpha is involved in the proliferation of CD4 cells [72], in the production of chemokines and cytokines [74] (IL-1), and is also involved in the process of apoptosis in certain types of cells [73].

The level of TNF-alpha correlates with disease activity [71], and TNF-alpha inhibitors have proven effective in the treatment of plaque psoriasis [72].

INFLAMMATORY CELLS IN PSORIASIS

Keratinocytes and cells of innate immunity in the skin

At the level of the skin, which is the largest organ of the body, consisting of the epidermis, dermis, and hypoderm [3], there is a large number of cells with various roles.

In psoriasis, the interaction between cells of the innate immune system (macrophages, neutrophils), cells belonging to adaptive immunity (T and B cells), and resident cells (keratinocytes, melanocytes) support chronic inflammation [73].

In the early stage of inflammation, an important role is played by dendritic cells, which are antigen-presenting [75]. The mechanism by which these cells are activated is incompletely elucidated, but it seems that there are certain microbial peptides, such as LL37, and S100, released by keratinocytes [76]. In psoriatic skin, these peptides are overexpressed and bind to the DNA of damaged cells, which causes dendritic cells to be activated to produce IFNα [77]. It (IFNα) causes the activation of myeloid dendritic cells [75].

Activated dendritic cells transform into antigen-presenting cells to be able to interact with naïve T cells and begin to produce large amounts of TNF-alpha, IL-23, IL-6, and IL-12 [77].

These cytokines activate the inflammatory cascade by recruiting neutrophils to the site of inflammation [78] and the proliferation of keratinocytes [79].

Keratinocytes, in turn, produce antimicrobial peptides [74], cytokines (IL-6, TNF-alpha), and chemokines (CCL20, CXCL5, CXCL9, CXCL10) [76].

IL-36, secreted mainly by keratinocytes and dendritic cells [73], accumulates neutrophil granules, present in large numbers in psoriatic skin [77]. IL-36 binds to its receptor IL-36Ra [78] and is involved in the transcription of other inflammatory mediators, by activating NF kappa B [79]. Also, IL-36 increases inflammation through its interaction with other inflammatory cytokines, such as IL-17 [79]. Some data suggest that decreasing the number of neutrophils significantly improves inflammation [76].

Macrophages are also antigen-presenting cells [75]. They derive from monocytes [77] and are involved in the occurrence of psoriasis inflammation [78], being an important source of TNF-alpha [77].

Within the innate immune system, cells without antigen-specific receptors (ILCs) are involved in antimicrobial defense and create a balance between pro- and anti-inflammatory factors [80].

ILC 3 can produce IL-17 and IL-2 [81], and their number decreases in the affected skin during the remission period of the disease [80], emphasizing the involvement in the pathogenesis of psoriasis, which requires additional data [81].

T cells

T cells have an important role in the defense against pathogens, and in the pathogenesis of psoriasis, there is an interaction with a central role between T cells and dendritic cells.

Dendritic cells release cytokines such as IL-12 and IL-23 that promote Th1, Th17, and Th22 responses.

At the epidermal level, T helper cells support keratinocyte hyperproliferation, leading to decreased apoptosis.

By carrying out human skin transplantation in SCID immunodeficient mice, followed by the injection of CD 4 T cells from patients with psoriasis, the role of these cells in the pathogenesis of psoriasis was demonstrated.

Th 1 (CD4+) cells produce large amounts of TNF-alpha and IFN-gamma involved in triggering psoriasis.

In mice with IL-17 receptor deficiency, skin inflammation is reduced, emphasizing the importance of IL-17 in the occurrence of psoriasis lesions.

Thus, elevated serum levels of IL-17 and increased expression in lesions are typical features of psoriasis.

After it was demonstrated that IL-23, produced by dendritic cells, is involved in the development of Th17, it became obvious that the IL-23/Th17 axis has an important role in the pathogenesis of psoriasis.

B cells

B cells are involved in the adaptive immune response through antibody production and antigen presentation [23].

Using a model of intestinal inflammation, Mizoguchi et al. [58] in a model of intestinal inflammation, showed that B cells produce IL-10 and thus have a protective role against inflammation.

Also through the secretion of IL-10, B regs cells are involved in alleviating various allergic and inflammatory diseases [82]. They do not represent a distinct lineage of B cells but are rather a subset of them [81]. It is not elucidated which factors are involved in the development of B cells in a type B regs [80].

The B regs cell population is characterized by the presence of CD5+CD1d hi on the surface [81].

Other subsets of B cells involved in the production of IL-10 are those in the marginal zone – CD19+CD21 hiCD23-CD24hi and CD138+ plasma cells [80].

Compared to T cells and studies regarding their role in the pathogenesis of psoriasis, in the case of B cells, data are limited regarding the involvement of these cells in psoriasis, as they rarely appear in lesional skin [83].

The decrease in the number of B lymphocytes in patients treated with anti-CD20 (Rituximab) for other autoimmune diseases led to the appearance of psoriasis skin lesions in individual cases [84].

B cells secrete inflammatory cytokines such as IL-6, IL-4, and IFN-gamma, being key effector cells [83].

Also, in a recent study, it was demonstrated that a large number of IL-6-producing B cells are found in inflamed mouse skin [80]. Blocking IL-6 resulted in reduced inflammatory symptoms [84].

DISCUSSION

In the case of mild psoriasis, the inflammatory process is confined to the skin, on the other hand, a more extensive active disease should be regarded as a systemic inflammatory disease, impacting internal diseases, including arthritis and metabolic syndrome [88].

Patients suffering from moderate to severe forms of psoriasis have increased serum levels of multiple proinflammatory cytokines, including TNF-a, IFN-c, IL-6, IL-8, IL-12, IL-17A, and IL-18 [89].

All the subtypes of T cells involved in the pathogenesis of psoriasis are also involved in atherosclerosis [90]. Sherlock et al. demonstrated that IL-23 drives inflammation in the aortic root through the activation of CD3+CD4−CD8− T-lymphocytes [91].

TNF alpha plays an important role in the inflammatory pathways of metabolic syndrome, diabetes, and cardiovascular disease. TNF alpha inhibitor therapy is associated with a lower risk of major adverse cardiovascular events (MACE) independent of traditional cardiovascular risk factors [92]. Recent research shows the importance of Th17 and other IL-17-producing cell types in the pathogenesis of cardiovascular events [90].

We lack large well-designed studies which prove the improvement of comorbidities by treating psoriasis with biologics.

In short term, there is evidence that early treatment with biologics reverses damage caused by inflammation. New biomarkers and early diagnosis help healthcare workers in better evaluation of patients' responses to systemic therapies [93].

CONCLUSIONS

Psoriasis is a recurrent, chronic, T-cell-mediated, polygenic disease characterized by erythematous squamous lesions in specific body sites. The pathogenesis of psoriasis is complex and still undergoing study. Biologic therapy is the key to reversing inflammations and preventing associated comorbidities.

Abstract: *Angiosarcoma is a malignant tumor derived from the endothelium of the blood and lymphatic vessels. Its aggressive behavior results in a poor prognosis for the patients. Radiation-associated angiosarcoma is a rare recently described particular subtype of angiosarcoma best shown in patients after treatment of breast cancer. The latency period of development is approximately 8 years, thus the 5-year standard follow-up after mammary neoplasm therapy needs to be extended up to 10 years. Radiotherapy is an independent risk factor for angiosarcoma development. Rapid diagnosis is essential for prompt therapeutical intervention to improve the patient's prognosis. The importance of early diagnosis is emphasized by a case of a 54 years old woman, with a diagnosis of breast cancer treated by sectorectomy and radiotherapy 7 years prior, presenting to our Dermatology Department for the recent occurence of erythemato-violaceous cutaneous patches on the area subjected to radiotherapy.*

Keywords: *angiosarcoma, radiation, radiotherapy, breast cancer, conservative surgery, follow-up*

INTRODUCTION

Angiosarcoma is a malignant tumor that originates in the endothelium of the blood and lymphatic vessels [1]. It usually develops in the skin, soft tissue, breast, or liver [2]. It comprises 1-2% of the soft tissue sarcomas that appear in humans [3], it is uncommon and affects mostly Caucasian men, with the highest incidence in adults over 70 years.

When it comes to younger ages such as children or adolescents, angiosarcomas are rare and are prone to develop in viscera or nearby, usually the heart, or they are associated with other conditions such as immuno-suppression, chronic radiodermatitis or lymphedema [4].

Risk factors associated with angiosarcoma include chronic lymphedema, radiation history, carcinogens (eg vinyl chloride, arsenic), and specific familial syndromes [3].

Angiosarcomas cells have endothelial differentiation and they clone while undergoing a malignant transformation. Unlike other sarcomas, angiosarcomas have a different upregulation of the genes responsible for the vascular receptors [4]. In angiosarcomas that have been induced by radiation or lymphedema, the amplification of MYC is high which in the end leads to the downregulation of thrombospondin-1, a protein that inhibits angiogenesis [4]. MYC is overexpressed in patients with radiation-induced angiosarcoma and this can help distinguish it from primary angiosarcoma [5]. Angiosarcomas can be well- or poorly differentiated; in the first case, one can observe vascular channels that are not regular in shape, they are lined by endothelial cells and they dissect the fibers of collagen; the latter has ill-defined vascular spaces, the cells are spindled, polygonal, epithelioid and round and they show multiple mitosis and big nuclei [1].

Immunohistochemistry is used when diagnosing less differentiated angiosarcomas. The cells express vascular as well as endothelial antigens such as Factor-VIII, CD31, CD34, and VEGF. CD31 is seen in more than 50% of the cases and has great sensitivity and specificity [3]. Recently, there has been used a marker called ERG, which is a member of the ETS family of DNA-binding transcription factors and which offers greater sensitivity and specificity for endothelial cell differentiation

[1].

PATHOGENESIS AND TYPES OF ANGIOSARCOMAS

The mechanism through which angiosarcoma may appear in chronic lymphedema is not well known, but theories postulate that some carcinogens build up in the lymphatic fluid and because the lymphatic network is lost, the affected area is spared by the immune system and this fact can furtherly favor the neoplastic modified cells.

An independent risk factor for the development of angiosarcoma is radiotherapy which is best shown in patients with breast cancer [4].

There are essentially 3 instances for the occurrence of cutaneous angiosarcoma: idiopathic angiosarcoma of the scalp, face, and neck, angiosarcoma associated with chronic lymphedema (Stewart-Treves syndrome), and post-irradiation angiosarcoma. Some authors describe a fourth type which occurs in any other settings than the previous ones [1].

Angiosarcoma of the scalp, face, and neck is most frequent in elderly individuals. Men are two times more affected than women. The lesion begins as a bluish macule that can be confused with a bruise.

Angiosarcoma associated with chronic lymphedema is also called Stewart-Treves syndrome and this type is seen in areas with long-lasting lymphedema as is the case of the upper arm after the patient underwent a mastectomy. The tumor develops 11-22 years after surgery, having though a low incidence of 0.45% of the cases, but a poor prognosis [6]. Other instances of chronic lymphedema may be parasitic infections or congenital lymphedema [3].

Post-irradiation angiosarcoma is a vascular tumor that appears in sites that have been irradiated in the past. If the affliction for which the patient has received radiotherapy was benign, the average time for angiosarcoma to develop is 23 years, but if the condition treated with radiation was malignant, then the time reduces to only 12 years [6].

The fourth type is uncommon and may appear for example in benign vascular tumors, in cases of immunosuppression after organ transplantation.

RADIATION ASSOCIATED ANGIOSARCOMA

The angiosarcomas that arise in areas of previous radiation sites are difficult to be differentiated from atypical vascular lesions. Sometimes even histologically, the diagnosis can be challenging since well-differentiated angiosarcomas which exhibit only minor cytologic atypia despite their aggressive behavior, may be similar to microcystic lymphatic malformation. Also histologically, the angiosarcoma must be differentiated from other vascular neoplasms such as PILA (papillary intra-lymphatic angioendothelioma), RHE, epithetlioid hemangioendothelioma, KHE (Kaposiform hemangio-endothelioma) [4].

Imaging tools such as CT, and MRI are helpful, but to have a precise diagnosis for angiosarcoma, histologic examination and immunohistochemistry of the tissue confirm the disease.

Post-irradiation angiosarcoma is not seen very often [1]. It is considered a late severe complication of radiotherapy [7]. The majority of cases emerge in the skin after it has been irradiated for breast cancer, or not so frequently, for a neoplasm of the internal organs [1]. Post-irradiation angiosarcoma has a cumulative incidence of 0.9-3.2 per 1000 cases of mammary neoplasm. In terms of prognosis, a 5-year survival rate lies between 27 to 48% [8]. If the patient had radiation therapy for breast cancer, the period after which a sarcoma in this area may appear is 5-10 years and this means that the usual 5-year follow-up needs to be extended [3]. It appears that other radiation-induced sarcomas take more than 10 years to develop [9]. Some studies link the usage of radiation in high doses with the incidence of angiosarcoma [3]. In the case of breast angiosarcoma, the latest population-based studies have shown the risk to be about 0.1%. It has been hypothesized that the replacement of radical mastectomies with conservatory surgery has led to secondary angiosarcomas in the mammary gland [10]. Breast angiosarcoma can be categorized into primary (de novo) if it develops without any known trigger, or secondary if it appears at the site of previously irradiated integument [8].

It appears that in the last few years, of all the subtypes of sarcomas of the breast induced by radiation, angiosarcoma had the highest occurrence [10].

In a retrospective Dutch population-based study from 2019 of 296,577 patients with angiosarcoma after breast cancer treatment (1989-2015), the median follow-up after diagnosis of breast cancer was 7.7 years, and the median age when diagnosed with angiosarcoma was 58 years. Of the 184,823 patients that received radiotherapy, only 209 had angiosarcoma of the breast and/or chest wall. As a note, angiosarcoma did not occur in any of the patients that did not receive radiotherapy (111,754). The median period between breast neoplasm treatment and the appearance of post-radiotherapy angiosarcoma was 8 years. In this study, 5- and 10-year survival rate was 40.5% and 25.2%, respectively, regardless of the type of treatment (surgery alone, surgery and radiotherapy combined sometimes with hyperthermia, chemotherapy, and radiotherapy). The inclusion of radiotherapy compared to only surgery had not shown a significant survival [7]. Another study from 2013, that evaluated 48 patients with angiosarcoma treated between 1990 and 2004 (7 with breast cancer) showed a 7 years latency period for angiosarcoma of the breast. [11].

Clinical presentation of cutaneous angiosarcoma includes single or multiple red, bluish or violaceous macules, patches, and nodules, that can further ulcerate or present intra-tumoral hemorrhage [6].

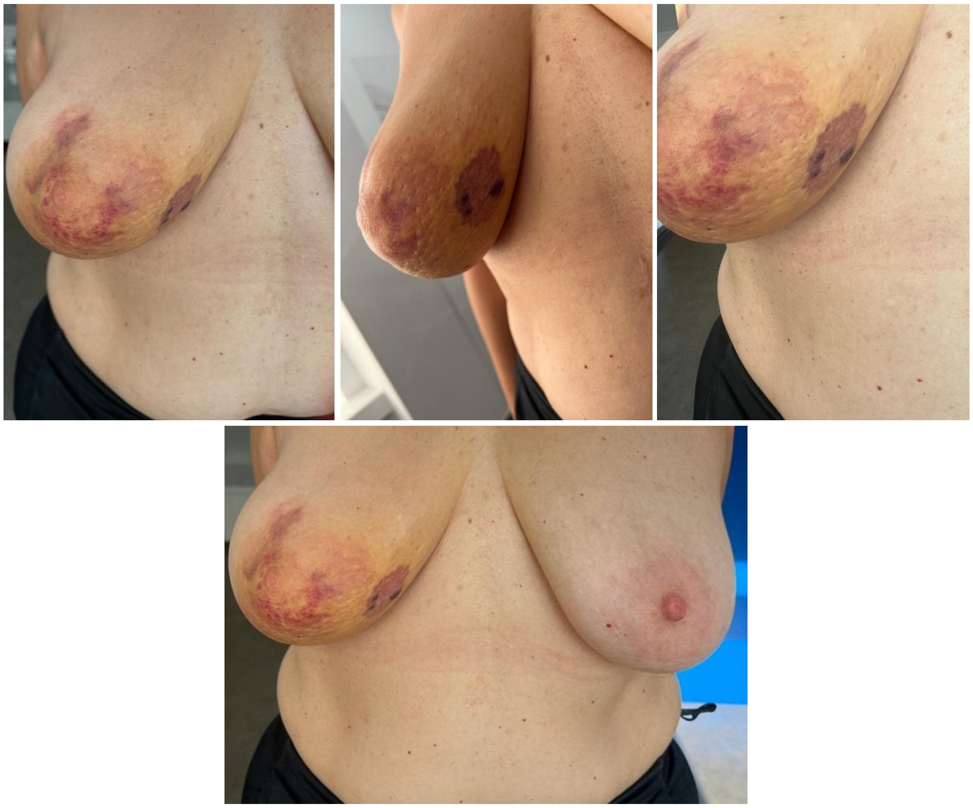
The 2022 diagnostic criteria for radiation-associated angiosarcoma are a) sarcoma that develops in a previously irradiated field or the tissue volume comprised in the 5% isodose line; b) minimum 4 years between radiotherapy and the arising of the angiosarcoma; c) histological difference between primary neoplasm and secondary sarcoma; d) the exclusion of patients with cancer syndromes [5].

The prognosis is poor because angiosarcoma is an aggressive tumor; patients' survival rate without treatment is between 6 months and 2 years after diagnosis [6]. If it is a low-grade tumor, it behaves similarly to atypical vascular lesions, but a high-grade angiosarcoma is aggressive, has violent growth, and local recurrences arise after a few months [9]. However, with an incidence so low, one can assume that it is worth risking the arising of an angiosarcoma in a patient with breast cancer for the benefit of radiotherapy on the primary neoplasm [8].

Treatment consists of surgery, radiotherapy, and chemotherapy as options, but the choices and results vary on tumor size, location, and type, and last, but not least, resectability [3]. Currently, the main choice is surgical removal [8]. For localized angiosarcoma, the mainstay of the treatment is surgical resection along with adjuvant radiotherapy. Recurrences are difficult to avoid; chemotherapy is the first option in case of metastatic angiosarcoma [3]. The recurrence rate of post-radiation angiosarcoma of the breast is high (96%) and metastases are most often found in the lungs and liver and they can coexist with the local recurrence or appear soon after [8].

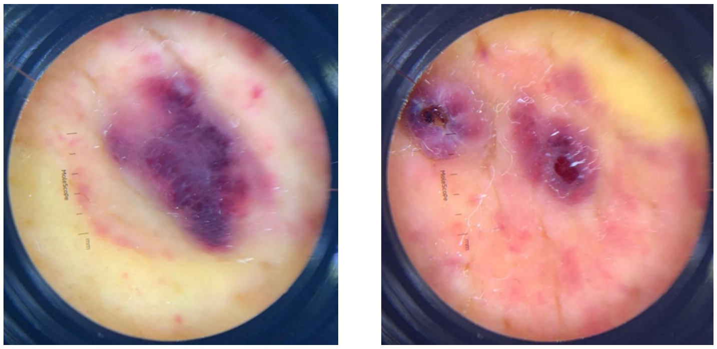
In a case of a 54-year-old woman who was referred to our clinic for ecchymotic and purpuric macules localized on the right breast, postradiotherapy angiosarcoma was diagnosed based on clinical aspect, history, histology, and immunohistochemistry. She had a previous history of sectorectomy for breast cancer 7 years prior and she also underwent radiotherapy. Clinical examination identified well-defined ecchymotic and purpuric macules, oval or with irregular polycyclic borders, 1-3 cm diameter; a similar macule located in the lower-inner quadrant, 4 cm diameter, with purple nodules on the surface, resembling Kaposi sarcoma (Figure 1).

Figure 1: Clinical aspect of the breast lesion



The lesions appeared 2 months before presentation, with progression in terms of dimensions and the number of lesions. The dermoscopic examination showed a combination of red, blue, and purple: a violaceous hue of the lesion that had purple clods with white structures, red and blue areas, and reddish-brown crusts that covered the central part of the nodules (Figure 2).

Figure 2: The dermoscopic examination



Skin biopsy of two sites was performed: a cutaneous nodule from the lower-inner quadrant of the right breast and a cutaneous fragment from the upper-outer quadrant of the right breast. The histology examination revealed: the first site showed ill-defined tumoral proliferation made up of randomly located oval/fusiform cells with elongated nuclei or grouped in short anastomotic bundles that defined small vascular spaces or intracytoplasmic slits without walls, some of them containing blood; moderated lymphoplasmacytic infiltrate and hemosiderin associated deposits. The second site of the biopsy had the same histopathologic description (Figures 3 and 4).

Figure 3: Dermal vascular proliferation, mimicking Kaposi sarcoma (HE X 10)

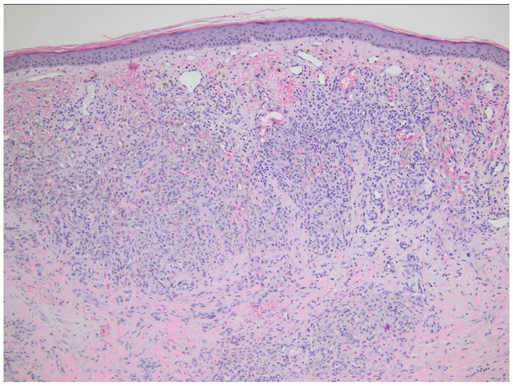


Figure 4: Dermal vascular proliferation, mimicking Kaposi sarcoma (HE X 20)

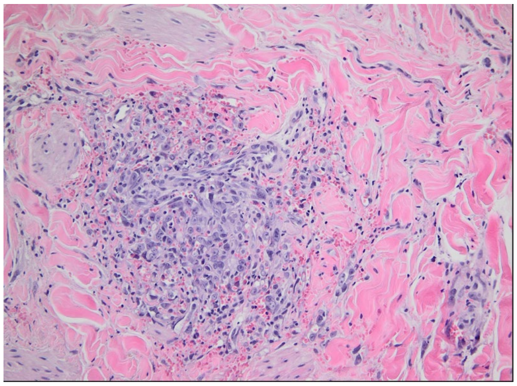

Was then performed immunohistochemistry tests for a positive diagnosis. These tests showed on both blocks HHV-8 negative and ERG and SMA positive, but c-MYC positive on the second piece of tissue (Figures 5-7).

The conclusion was that of a postradiotherapy angiosarcoma. The patient was then referred to Oncology Department for further investigations and therapeutic intervention.

Figure 5: C-MYC positive within numerous tumor nuclei

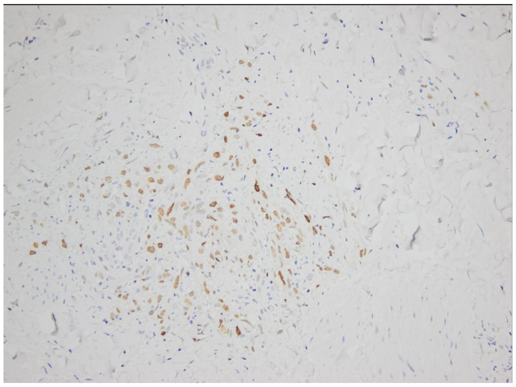

Figure 6: SMA positive within scattered tumor cells

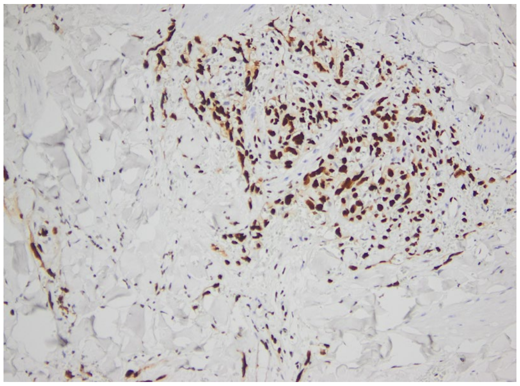

Figure 7: ERG positive within numerous tumor nuclei

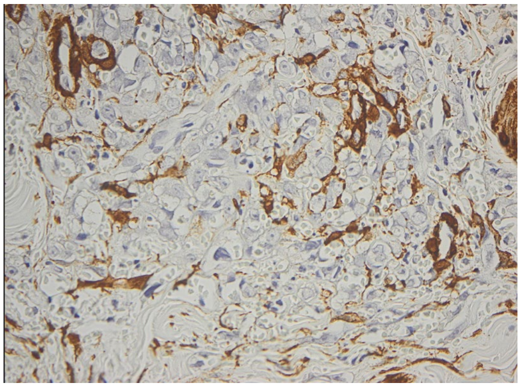

CONCLUSIONS

- Radiotherapy is an independent risk factor for the development of angiosarcoma, best shown in patients with breast cancer.
- Post-irradiation angiosarcoma has a cumulative incidence of 0.9-3.2 per 1000 cases of mammary neoplasm so it is a rare complication of radiotherapy, proving to be a challenging clinical diagnosis.
- The diagnosis of angiosarcoma can also be histologically challenging – it can exhibit only minor cytologic atypia in well-differentiated cases; immunohistochemistry testing is essential for differentiation from other types of sarcoma (including Kaposi sarcoma).
- The average period between breast neoplasm treatment and the appearance of post-radiotherapy angiosarcoma is 8 years.
- Prognosis of RAASB is poor, 5-year survival rate lying between 27 to 48% and thus it needs rapid diagnosis and therapeutic measures.
- 5-year standard follow-up after breast cancer needs to be extended up to 10 years to capture the development of an angiosarcoma.

Abstract: *Pheochromocytomas are rare neuroendocrine tumors that frequently have genetic involvement and can present a particular risk in terms of the anesthetic-surgical procedure. Current worldwide medical recommendations state that laparoscopic adrenalectomy is the conventional treatment for pheochromocytoma, however, the ideal surgical strategy is still being developed as specialized surgeons gain experience with these rare tumors. The study's purpose was to thoroughly evaluate our film library and identify the best surgical steps that represent our standardized procedure. We developed a comprehensive set of surgical critical strategies for either a left or right adrenalectomy, providing helpful advice on patient positioning, port placement, the adrenal gland approach, as well as other surgical methods specifically designed for tumor mobilization and dissection. The current paper aims to synthesize our clinical experience in terms of preoperative preparation, patient positioning, intraoperative complications, causes of conversion, and specimen extraction. The main conclusions concern both the best surgical approach and the importance of surgical experience in the clinical management of these rare tumor types.*

Keywords: *pheochromocytomas, laparoscopic adrenalectomy, surgical strategy*

INTRODUCTION

Pheochromocytomas are relatively uncommon tumors often with genetic aggregation that is accompanied by a high risk of overall morbidity and mortality, especially during surgical procedures precipitated by important blood pressure and heart rate variations. Although laparoscopic adrenalectomy has become a standard procedure for pheochromocytoma, the optimal approach continues to evolve as surgeons develop expertise in this pathology.

MATERIALS AND METHODS

Our experience starts almost 20 years ago, counting 436 laparoscopic adrenalectomies, from which 96 were performed for pheochromocytoma. We systematically reviewed our video database and highlighted the best surgical steps that exemplify our standardized approach.

RESULTS

From our experience, we managed to synthesize detailed surgical key steps for the overall procedure when performing left or right adrenalectomy, offering valuable tips starting from the patient positioning, and port placement and continuing to the adrenal approach, along with different strategies specifically tailored for pheochromocytoma mobilization and dissection. Taking into consideration our experience in dealing with the challenges of this procedure the current article aims to lead to improvement of overall outcomes for this procedure.

Preoperative preparation

From the anesthesiologist's point of view, surgical resection of pheochromocytoma can be divided into two phases based on the ligation of the tumoral blood supply [1]. Communication between the surgeon and the anesthesiologist regarding the surgical steps, in particular the ligation of the central adrenal vein, allows a proactive attitude, foreseeing the eventual intraoperative hemodynamic variations.

The first part of the procedure refers to all the surgical and anesthetic steps before ligation of the central adrenal vein in which severe episodes of cardiac arrhythmias and hypertension can occur [1].

The second part refers to all the surgical events that follow the central adrenal vein seal and it might be characterized by a sudden decrease of arterial blood pressure and in intravascular volume that might require vasopressor support [1].

Keeping in mind the possible cardio-circulatory outcomes during this surgical procedure, large-bore venous access should always be obtained [2], the guidelines also recommend continuous intraarterial blood pressure monitoring for all patients with pheochromocytoma or at least for those with persistent preoperative hypertension [3–5].

Adding a central venous catheter allows secure and effective administration of vasoactive medication to promptly counterbalance the hemodynamic variations, especially since there are no accurate predictors of which patients are most likely to need central administration of vasopressors [2,4].

In our experience, the availability of 2 large-bore venous access associated with good preoperative management with stress minimization and anxiolytic administration, decreases the sympathetic nervous stimulation, that might trigger a hypertensive crisis [6,7], was enough to ensure rapid and effective administration of intraoperative drugs. Frequent non-invasive blood pressure measurement (every 3 minutes) and close communication with the surgeon regarding the current, the following, and the particularities of the ongoing surgical steps supply all the data needed to fine-tune vasoactive drug administration even without intra-arterial continuous blood pressure monitoring.

Although not routinely recommended, at the beginning of our experience we chose to perform a mild bowel preparation the day before the surgery (polyethylene glycol), a practice that we later abandoned as we saw no intraoperative benefit in terms of bowel injury or postoperative bowel movements. More than that, some of the cases presented a distended lumen at the time of surgery, especially for the left colonic flexure, and this was disturbing the surgical dissection.

Patient positioning

Our experience refers only to the transperitoneal approach mainly due to the familiarization with the peritoneal cavity as general surgeons. In all our cases we used the lateral trans peritoneal approach because it usually offers a larger surgical field that is particularly useful in the case of large tumors such as pheochromocytomas and morbidly obese patients.

The standard patient position for laparoscopic adrenalectomies is in contralateral decubitus [8,9] with the possibility of a backward tilt up to 30° [5]. After anesthesia induction, a nasogastric tube (especially useful in left-sided adrenalectomies), and urinary catheter insertion, the patient is placed in lateral decubitus. Prevention of contralateral brachial plexus injury was done using a soft roll under the contralateral axilla. The other arm is can be elevated and secured on an elevated arm board [8] but, in our experience, we placed the ipsilateral arm slightly bent, in a relaxed position over the other one without needing rigid support or any other fixation method.

Keeping in mind the unpredictable hemodynamic events that characterize pheochromocytomas during adrenal surgery, the patient's position has to offer both good access to the tumor and also the possibility to finish the surgery openly due to conversion in an emergency setting. The umbilicus is placed above the surgical table breakpoint that is next flexed and tilted in an anti-Trendelenburg position until the ipsilateral flank contour is stretched to a straight line which we position parallel to the horizontal line. Over-flexing the operating table can cause supplementary tension of the abdominal wall thus causing less compliance, less working space, and consequently need for increased pneumoperitoneum pressure [8]. These patient position landmarks provide a maximum distance from the anterior superior iliac spine and costal margin offering a large operating field and increased ergonomic for the surgical team even for large tumors – the patient “needs to open” as much as possible the space between rib’s rim and the iliac crest. Depending on the high conversion probability (large tumoral size, retrocaval positioning, and hemodynamic variability) we tilted the patient back up to 30° using shoulder and hip supports. The patient’s legs are a little bit flexed to avoid stretching the crural nerve. Additional fixation was achieved using cloth straps at the hip and leg level.

According to the literature, trocar placement is variable. All ports are inserted at least 2 cm from the rib’s margin. Pneumoperitoneum is achieved in open maneuver, and then the first 10 mm trocar is inserted between the anterior axillary line and midclavicular line, depending on the exposure of the operating field (first, we palpate the inferior edge of the liver and – when is possible – the fundus of the gallbladder, then we decide to insert the trocar laterally to the gallbladder with a parallel direction to the trajectory of the inferior vena cava). Other three 10 mm trocars are inserted under direct visualization equidistant from each other (at least one hand distance), in the lateral border of the rectus sheath, another in the midaxillary line, and for retraction, one below the xiphoid process [10]. In all the laparoscopic adrenalectomies performed in our hospital, we used the Veress technique for the pneumoperitoneum, and the first skin incision was made in the midclavicular line at 3-4 cm from the rib’s margin. Only in obese patients, pneumoperitoneum was realized at 2 cm from the rib margin because CO_2 abdominal distension would move the incision further caudally causing a suboptimal visualization of the surgical field. All surgeries were performed with 4 trocars (we didn't experience a surgical adrenalectomy with 5 or more additional trocars): below xiphoid process for retraction, on the axillary line below the 10th rib (12 mm – used also to extract the specimen), and one at the half distance between the sub-xiphoid and optic trocar. The peritoneal space is insufflated to 12 mmHg using slow or medium flow insufflation as it is known that, intra-abdominal insufflation during laparoscopic pheochromocytoma excision may cause an increase in serum catecholamines [5,11] – Consequently, we strongly advise for taking enough time to realize the proper intra-abdominal pressure using small quantities of CO_2 inflated in at least 5 minutes (break times can be used!). During this time, the blood pressure of the patient should be carefully observed by the anesthesiologist and a trend to increase should be instantly corrected but not using too many anti-hypertensive drugs (risk for severe hypotension and rebound). Usually, the failure of this operative time is solved by conversion to open surgery, with rapid recovery of the blood tension being noticed with no major anesthesia intervention.

It is known that during surgery for pheochromocytoma, there is a risk of a hypertensive event due to catecholamine secretion – it could be beneficial for the patient to use a decreased level of pneumoperitoneum – like 11 mmHg, even 10 mmHg – if the working camera is allowing you proper movements of the instruments. Many surgeons highlighted that early ligation of the adrenal vein is an important goal in adrenalectomy, but studies have shown that delayed vein ligation does not appear to cause significant hemodynamic variation during laparoscopic adrenalectomy for pheochromocytoma [12,13] and taking into consideration that the dissection of the adrenal vein as the first step of the adrenalectomy, can be more demanding in case of large size adrenal lesions such as pheochromocytomas, we did not routinely approach the adrenal vein first (unless it was identified from the very first beginning), and we did not encounter intraoperative cardiovascular complications. Laparoscopy offers a real-time surgical overview to the anesthetic team that can anticipate when the adrenal vein is ligated and take steps to avoid cardiopulmonary complications.

Even from the insertion of the camera, a full video inspection of the peritoneal cavity should be done to evaluate the availability of other trocar entry sites. The presence of intraperitoneal postoperative adhesions can change the trocar order so that the operating field and other trocar entry sites can be conveniently exposed. In particular, placement of the lateral port in left adrenalectomies requires, in most cases mobilization of the splenic flexure and descending colon incising the peritoneum along the white line of Toldt. The viscera surrounding the adrenal gland are inspected for invasion: the spleen, the diaphragm and the greater gastric curvature (on the left side) and ascending colon, the liver, the right kidney, the diaphragm, and the duodenum (on the right side) are inspected and if there are suggestive signs of malignancy, conversion is mandatory [8]. Before beginning the laparoscopic adrenalectomy we should keep in mind that pheochromocytomas are larger than other adrenal tumors and, in our experience, they also have a frail consistency with a thin capsule and an increased number of arteries and veins that easily bleed on manipulation. This is the reason we advise having proper laparoscopic equipment and also alternatives to ensure good hemostasis and vessel sealing as well as to strictly follow the rule of "dissection of the body from the gland instead of dissection of the gland from the body" (Prof. J Marescaux, Strasbourg, France – off-the-record).

On the right side, while the liver is retracted cranially and medially so that the peritoneal reflection is seen and the left-right triangular ligament is tensioned and divided; the peritoneum is incised along the liver as far on the diaphragm so that the right lobe of the liver gently falls away medially. The posterior peritoneum is incised along its reflection on the inferior liver margin. The inferior vena cava (IVC) is identified and the peritoneum along its lateral margin is incised until it meets the hepatic parenchyma. The literature defines the caudal limit for the peritoneal division along the IVC as the superior edge of the renal vein [14] in our experience identifying this landmark might require unnecessary touching of the pheochromocytoma, especially in patients with well-represented retroperitoneal fatty tissue. When dealing with pheochromocytoma we use the macroscopic inferior border of the adrenal tumor as a landmark for inferior peritoneal division, as these tumors tend to be larger, carefully not to damage the inferior arm of the adrenal gland.

On the left side once the hepatic flexure and descending colon have been retracted medially by following the space between the Gerota's fascia and the mesocolon [8]. The next step ensures a good mobilization of the spleen and is carried out by division of the phrenicosplenic ligament starting at the posterior and inferior margin of the spleen and continuing cranially until the fundus of the stomach is visualized. Although the literature mentions visualization of the left diaphragmatic crus as the end landmark of this dissection [8], in our experience this was rarely needed. Medial mobilization of the spleen during this step can be performed with gentle retraction or, as some authors recommend, leaving a 2 cm peritoneal margin attached to the inferior margin of the spleen to grasp [8]. Usually, this is the moment when accidentally puncture of the splenic parenchyma is performed due to aggressive manipulation of the laparoscopic instruments – minor bleeding can occur and immediate hemostasis should be performed using hemostatic agents like oxidized regenerated cellulose or other topical fibrin sealant patch (sometimes, when a simple injury of the spleen capsule is noticed, it is enough to apply a pad pressure onto the injured area for a few minutes). Once the spleen is fully mobilized it will fall medially along with the tail of the pancreas exposing the lateral edge and anterior portion of the left adrenal gland [9]. Correctly fulfilling this surgical step ensures access to the right dissection plane thus avoiding blind dissection into retroperitoneal fatty tissue which is prone to excessive bleeding and capsular breaking, forbidden when resecting pheochromocytomas.

Partial adrenalectomy avoids the need for life-long hormone replacement and it is usually useful for patients with bilateral gland involvement. This procedure is performed in small tumors located on the periphery of the affected adrenal limb. Performed in pheochromocytoma has a high risk for intraoperative hypertensive crisis due to tumor manipulation and thus early identification of the adrenal vein is mandatory before partial resection [15]. For partial adrenalectomy to be feasible the remnant gland to have a good vascularization, so laparoscopic ultrasonography to evaluate the adrenal gland viability must be recommended [16]. Because of the risk of bleeding in partial adrenalectomy, it is preferred safety surgery and total adrenalectomy be performed.

Once the periglandular dissection is started it is important to keep in mind a principle postulated even from the first adrenalectomies, and demonstrated in later studies: a mean increase in plasmatic catecholamines up to 34-fold during tumor manipulation [17-19]. To minimize hemodynamic instability, these techniques require minimal to no direct manipulation or compression of the tumoral gland [5], achieved in many cases by gentle retraction of the surrounding viscera or tissue such as the kidney, pancreas, and liver or by using periglandular fatty tissue, the Gerota's fascia and/or the disconnected vein stump, to manipulate the gland accordingly. Comparing pheochromocytoma ablation with other types of adrenal tumors, it is mandatory to respect the principle of "dissecting the patient away from the tumor" to achieve this important goal [20]. In large tumors with which we encounter technical difficulties prompt conversion has to be taken into consideration to reduce the patient's risk for capsular disruption and following iatrogenic disease recurrence [5] or even pheochromocytomatosis [14]. As mentioned before, pheochromocytomas have numerous tributary vessels that combined with the frail vascular wall and increased circulatory catecholamines represent the optimal recipe for possible uncontrollable bleeding, so achieving a proper vessel seal before tissue dividing is mandatory even with the usage of clips as a complementary method to the electrocoagulation and sealing devices [5].

For the right-sided adrenalectomy, the lateral border of the IVC continues to be the main landmark during the procedure allowing lateral retraction of the adrenal gland and thus exposing the central adrenal vein. Even though it is more demanding, many authors concluded that once the peritoneum is incised, as mentioned before, the tumoral gland should be approached first on the medial border – detaching the tumor from the IVC, exposing, clipping, and dividing the central adrenal vein [8]. The dissection continues along the inferior border of the adrenal gland and might include the peri-adrenal fat. The adrenal is gently lifted and the posterior aspect is released and then the lateral one. The final step is detaching the superior border of the tumor [8]. We share the opinion that first freeing the inferior and posterior aspect of the gland assures enough mobility to safely push the gland laterally, without manipulation or grasping, increasing the space to the IVC, exposing the central adrenal vein, and more important, pulling the adrenal tissue situated posterior to the IVC. While this approach carries a higher risk of capsular breaking when beginning the dissection, it offers more control and better retraction in dealing with the main vascular pedicle and retro-caval adrenal tissue. The dissection continues cephalad until the medial side of the gland is released and further on the superior edge.

Once the central adrenal vein is secured, we can better manipulate the tumoral gland. In large tumors, some authors recommend starting the dissection from the lateral and superior border of the tumor and then moving inferior to the IVC [8].

For the left adrenalectomy, it is generally accepted that the dissection begins along with the medial border proceeding from the upper to the lower adrenal pole, keeping close to the posterior muscular plane. This maneuver allows lateral rotation of the adrenal and exposes the left adrenal vein that will be ligated early in the dissection. During the dissection of the medial border of the adrenal gland, the inferior diaphragmatic vein might be encountered and it represents a landmark for the central adrenal vein. Particularly in pheochromocytomas, starting the dissection from the lateral border should be avoided since it will cause the gland to rotate inferiorly and medially thus requiring increased manipulation and pulling the adrenal gland, in order to access the central adrenal vein. After securing the central adrenal vein, the gland is lifted and the dissection continues at the posterior and lateral aspect of the gland, leaving the upper adrenal pole to be approached as last surgical gesture [8,14].

Several factors as the lack of major anatomic landmarks, the relative profound in the retroperitoneal fat of the left adrenal gland, with the main vein within the retroperitoneal fat, the proximity and tissue similarity with the pancreas tail, may render the left adrenalectomy more difficult [8], especially in the settings of mandatory minimal glandular manipulation and compression, and forbidden cellular spillage. So, it is recommended for beginners to start laparoscopic removal of a pheochromocytoma on the right side, then the left side.

Taking into consideration that the retroperitoneal space contains the kidney, adrenal gland, and fatty tissue, it is very important to localize the adrenal gland within the surrounding fat. To avoid capsular breaking, especially in smaller-sized tumors perinephric fat containing the adrenal gland should be dissected away from the transversus abdominis muscle (laterally), the diaphragm (above), the *quadratus lumborum* muscle (posteriorly), and the pancreas or liver (medially on the left and right sides, respectively) just inside Gerota's fascia. During the separation of the perinephric fat from the diaphragm at the upper pole of the adrenal gland, the superior adrenal vessels are usually encountered and must be, carefully sealed and transected (especially in patients with large pheochromocytomas). During en bloc dissection, the perinephric fat is divided between the adrenal gland and the upper pole of the kidney using a vessel-sealing device. Next, the adrenal gland is lifted by grasping the periadrenal fat. The inferior and posterior adrenal vessels are in this way intercepted in the periglandular fat, sealed, and transected leaving the adrenal vein exposed between the gland and the inferior vena cava (right) or renal vein (left) [22]. At this moment (depending on the surgeon's experience, vessel diameter, and available surgical devices), the adrenal vein can be clipped or sealed leaving only the division of the remaining peri-adrenal fat to completion of the adrenalectomy. As a result, the adrenal gland will be removed along with its surrounding fatty tissue.

The technical feasibility of laparoscopic adrenalectomy for large pheochromocytomas in today's surgical activity is no longer a rarity [23,24]. Large right-sided tumors may be technically more challenging because of the operating space, which is limited by the liver with the inferior vena cava compressed and displaced anteriorly by the tumor, sometimes taking a lenticular shape on the medial margin of the tumor. However, large left-sided pheochromocytomas are also a source of complications. Our experience counts 23 pheochromocytomas larger than 6 cm and our intraoperative strategy is in concordance with other authors' opinions performing systemic peritumoral dissection, without manipulation of the tumoral gland, without the previous approach of the adrenal vein [25]. The purpose is to progressively free the tumor from the surrounding tissue and to take maximum advantage of gravity in achieving exposure. Another useful tool, in our experience, was the blunt 10 mm vessel seal and dividing device that helped not only achieve good hemostasis in the peritumoral fat but also protect the capsule from rupture, not mentioning also a speedy surgery timing.

Intraoperative complications

Laparoscopic adrenalectomy is considered to be the gold standard for surgery to remove the adrenal gland. Still one of the factors for intraoperative complication occurrence is pheochromocytoma along with the tumor size, surgical inexperience, patient age, and body mass index [26]. The most common intraoperative complication is hemorrhage which is in most cases possible to control in the hands of a surgeon with good laparoscopic skills and experience. Conversion to open surgery dropped from 6% in some early studies [27] to 0.6% [28]. Bleeding in a hypertensive crisis can occur from small vessels that are why special attention has to be paid to hemostasis. If proper electric hemostasis cannot be achieved and if it affects the safe dissection, applying a large gauze and pressing it into the bleeding area, was in our experience the best way to manage this situation until a clip was applied to control the bleeding. Apart from general complications during laparoscopic adrenalectomies specific aspects are related in particular to the pheochromocytoma, large tumors with important retro-caval development that compress the IVC anteriorly, present a high-risk caval injury that mandate conversion to laparotomy in most cases. Other vascular or visceral lesions can be caused by the large tumoral volume, specific to pheochromocytomas, and the need to mobilize the surrounding tissues instead of the gland, to avoid both catecholamines release or capsular breaking are the renal and the splenic veins. Major vascular injuries are recognized instantly during dissection, and it is important to evaluate the chance of controlling them laparoscopically, and not waste time converting to an open procedure [29]. Liver, pancreatic and splenic injuries are mostly due to adhesions, the presence of a large tumor or unexpected excessive tissue retraction to protect or better access the pheochromocytoma. In our experience, no solid organ injury during pheochromocytoma minimal invasive surgery forced us to convert to open surgery.

Causes of conversion

A large multicenter study showed that unplanned conversion to laparotomy during laparoscopic unilateral adrenalectomy for pheochromocytoma was independently associated with increased intraoperative hemodynamic instability episodes and postoperative complications rate [30,31]. Studies revealed that the ratio of intraoperative systolic blood pressure >200 mmHg and the total anesthesia time was an independent factor associated with conversion [32]. Although controversial intraoperative hemodynamic instability remains an important marker of the quality of pheochromocytoma manipulation during the surgery [32,33].

Another particular case of conversion in this type of tumor is represented by tumoral spillage not only due to the high risk of relapse [5,23] but also because of the high risk of undiagnosed malignancy [34], especially taking into consideration that in pheochromocytoma radiographic and histological information, including intraoperative frozen section examination, are unreliable predictors of malignancy [35,36].

However, conversion to an open procedure is warranted when laparoscopic dissection cannot be performed safely or a complete resection cannot be performed without undue trauma to the gland.

In our experience, conversion during laparoscopic adrenalectomy for pheochromocytoma was needed in 9 cases: 1 case of severe cardiac arrhythmia with cardiac arrest that required resuscitation on the operating table, 3 cases of invasive malignant pheochromocytoma, 2 cases large tumors that could not be dissected safely, and 3 cases of major vessel lesions: two inferior vena cava lacerations and one left renal vein injury.

Specimen extraction

Special care should be paid to the adrenal specimen since it might spill and contaminate the peritoneal cavity causing disease recurrence [5] or even pheochromocytomatosis [14]. This is why immediately following specimen detachment it is introduced in a retrieval bag for the following surgical steps like controlling hemostasis. Manipulation during this step should follow the dissection principles since the pheochromocytoma capsule can rupture under its weight if it is uncarefully manipulated. We recommend grasping the specimen using periglandular tissue, fascia, or vascular stumps to place it in the bag. We retrieved the bag always through the lateral incision that is enlarged accordingly to the specimen size, avoiding morcellation and contamination of the wall.

We also routinely drained the adrenal lodge, the drainage tube being exteriorized through the same incision from the specimen was retrieved. The tube stays in place for 24 hours if no bleeding is noticed.

Special attention to malignant pheochromocytoma was given to achieve an en-bloc excision of the tumor with wide surgical margins and as much peri-adrenal tissue as possible. The need to operate around the renal artery and vein or the renal hilum for achieving an en-bloc resection along with the peri-adrenal does not mandate conversion to laparotomy. However, conversion to an open procedure is warranted when laparoscopic dissection cannot be safely performed or a complete resection cannot be performed without undue trauma to the gland [5]. Hand-assisted laparoscopy is a good alternative to open conversion if a difficult dissection is encountered intraoperatively [37].

CONCLUSIONS

The best way to improve is to repeatedly follow a correct surgical pathway even from the beginning, especially when approaching a pathology with great morbidity related strictly to the delicacy and correctness of the surgical act. Experience of the high volume centers translates into excellent outcomes, achieved by minimizing complications, decreasing blood loss, and shortening hospital stays.

Abstract: *Melanoma is one of the most common types of malignancy in the world, and one known to carry a very poor prognosis until recent years. This review aims to outline the events in the history of the disease and the impact made by the discoveries along the way, as well as the modern-day consensus by referencing the updated literature regarding the present approach and future directions. In the last two decades, several studies and research have brought significant improvement in the diagnosis and clinical management of melanomas. The development of sentinel lymph node biopsy has brought major changes to the surgical approach to the disease, and modern therapies based on recently developed knowledge changed the death sentence this diagnosis once meant to a manageable condition despite its aggressiveness, keeping in mind that early diagnosis and safe margin excision remain the best and most optimistic course of treatment.*

Keywords: *melanoma, surgery, Breslow, Clark, lymphadenectomy, BRAF, immunotherapy, sentinel lymph node biopsy*

INTRODUCTION

Malignant skin tumors are among the top 10 causes of disease burden worldwide. 18.8 million new cases of cancer have been diagnosed in 2018 alone, with breast, lung, and colorectal cancer being the most frequent. It is also the second most frequent cause of death, preceded only by ischemic heart disease [1]. While skin cancer is not among the highest incidence malignancies overall, they do represent the most common malignancy in the white population. Furthermore, melanoma has had the highest increase in incidence rates – 5-fold in the past 30 years [2]. Therefore, reducing disease burden and mortality has become public health priority. Numerous studies and research have brought significant improvement in the diagnosis and clinical management of skin cancers, especially in the case of melanomas, which carried a very poor prognosis until recent years. Part of these improvements is due to the development of genetic testing for specific mutations and the subsequent development of targeted therapies. These have led to the increased survival of numerous patients and to important changes in the way this pathology is managed. Surgical excision has always held a central role in melanoma therapy, and it naturally changed and adapted along with newer treatments.

HISTORY OF MELANOMA DIAGNOSIS AND TREATMENT

The word "melanoma" originates from Greek ("melas" meaning "dark" and "oma" meaning "tumor") and it was described for the first time in recorded history by Hippocrates in the 5th century BC. The earliest physical evidence of melanotic tumors dates from around the same time and was found in the bones of pre-Colombian mummies [3]. Throughout the following centuries, more reports of such pigmented tumors were made, though not much was understood about their origin and development. In 1806, Rene Laennec introduced the term melanosis to describe the disease as a separate entity and demonstrated the difference in its structure from other dark-colored lesions found in autopsies, such as carbon deposits in the lungs [4]. The first thorough study of the disease was made by William Norris in 1830, who followed up a patient for 3 years, described the condition clinically and the autopsy findings in detail, including the vast number of metastases, their macroscopic structure, and the hereditary character of that particular case. He was also the first one who, in later studies, highlighted a possible link between "melanosis", and noticed a correlation between the condition and light-colored skin and hair [5]. The term "melanoma" was introduced in 1838 by Robert Carswell, who studied and described melanoma metastases, including brain localization, in detail [6]. A comprehensive analysis of primary tumors was also provided by James Paget in 1853, including the first description of the transition between a radial growth phase and a vertical growth phase [3,7].

In the 20th century, research techniques improved, and more effort was made to understand the disease and structure its treatment. In 1953, Spitz and Allen observed that nodular (or “deep”) melanomas have a worse prognosis than superficial melanomas [8].

In 1954 Ackerman and Del Regato were the first to propose a staging system, comprising four groups: a – patients with the generalized disease, b – patients with clinical lymph node disease, c – patients with infra-clinical (histological) lymph node involvement, and d – patients with primary tumors. The system was based on the observation that the latter group demonstrated improved survival compared to the first group, but not much difference was observed between the two middle groups [9,10].

With time, other stage systems were developed and proposed for clinical practice, such as the one designed by McNeer and Das Gupta in 1964, which comprised three stages based on disease extension and is regarded as a precursor to the modern TNM staging system [11]. This system was expanded and improved by the MD Anderson Hospital in 1976 [12], but it still had some shortcomings, such as failing to consider the pathology of the primary lesion.

In 1969, Clark, improving earlier systems proposed by Petersen (1962)[13] and Mehnert and Heard (1965)[14], based on the microscopic aspect of the primary tumor, presented the five levels of invasion still in use today [15]. One year later, in 1970, Breslow demonstrated the importance of primary tumor thickness in overall prognosis and survival [16].

With later studies corroborating their findings, such as McGovern’s for the Clark index [17] and Balch’s for Breslow – which also proved that tumor thickness is more relevant for prognosis than the level of invasion [18] – these characteristics of the primary lesion were added to later staging systems. Over time, the American Joint Committee for Cancer (AJCC) and the Union Internationale Contre le Cancer (UICC) have made several attempts to establish a simple, relevant, and coherent staging system that could be applied internationally.

Following a series of proposed systems that were only partially satisfactory, and after adapting to encompass new findings, in 2002 the AJCC proposed the modern staging system, whose updated version (8th edition) is in use today [19,20]. It includes ulceration of the primary lesion as a prognosis factor, uses the Breslow index as a primary determinant of T staging, with the Clark level used only for thin tumors (<1 mm), and makes a clear distinction between clinical and pathological staging. It also takes into consideration additional prognostic factors such as age, gender, tumor location, and histological subtype.

Melanoma treatment evolved as the understanding of the disease grew. The first surgical resection of such a lesion in Western medicine was performed by John Hunter in London in 1787 [3]. By the end of the 19th century, it became clearer that surgical excision is an appropriate course of treatment, with some authors such as Herbert Snow advising adjacent lymph node resection, while William Handley suggested a 5 cm of healthy tissue around the tumor along with extensive lymph node excision [3]. This remained the standard for melanoma surgery well into the 20th century.

After Clark and Breslow’s studies on the importance of primary lesion thickness in the prognosis of melanoma, surgical therapy was gradually adapted to decrease morbidity after extended excisions. A series of studies in the 1990s up to the early 2000s aimed to determine the optimal resection margin for each primary tumor stage.

Eventually, a relative consensus was established for safety margins of 0.5 cm for melanoma in situ, 1 cm for invasive melanoma <1 mm thick, and 2 cm for a Breslow index of >2 mm with some debate still ongoing about the optimal resection margin for tumors between 1 and 2 mm thick [21].

As mentioned previously, complete radical lymphadenectomy was performed as part of the surgical treatment for melanoma for most of the 20th century. The argument behind the indication was based on extensive studies on lymphatic drainage made by Rudolph Virchow and by Marie Sappey in the later part of the 19th century, and was supported and practiced by prominent surgeons like William Halsted for breast cancer in the US and, as mentioned before, by Herbert Snow for melanoma, in Britain [22].

Lymphadenectomy became an essential step in the oncological resection of various tumors for almost a century. By 1990, lymph node dissection was still performed as standard of care in melanoma treatment, whether electively (for clinically normal nodes) or therapeutically (for clinically evident lymph node involvement), but the need to find a better approach was frequently discussed, especially for small primary tumors and no clinical lymph node involvement [23].

In 1992, Morton and Cochran published a study that demonstrated the dissemination of tumor cells through lymphatic vessels first to a specific, identifiable node, called the sentinel node, then to other regional nodes [24]. They were not the first authors to use the term “sentinel node”, the term had been used previously by several authors to describe the first nodes draining specific areas on the body, but based primarily on their anatomy rather than physiology [22]. Morton used the technique described by Gerota who used a blue dye to map lymphatic vessels and introduced lymphoscintigraphy for patients with axial melanoma to determine the primary draining basin [25]. Their studies were not accepted easily, but as data continued to support their findings, sentinel lymph node biopsy became an integrated part of melanoma treatment.

GENETIC MUTATIONS IN MELANOMA

It is now understood that cancers are the consequence of a series of mutations in genes that control the proliferation, differentiation, and programmed death of the affected cells. In 2002, Davies and colleagues demonstrated a significant presence of BRAF mutations in human cancers [26]. BRAF (v-RAF murine sarcoma viral oncogene homolog B1), a proto-oncogene, is a RAS-regulated serine-threonine kinase and an activator of the MAPK signaling cascade. It plays an important role in cell differentiation, proliferation, and death through extracellular signals. The mutation was found in several malignancies, including melanoma, colorectal cancer, adenocarcinomas of the lung, sarcomas, ovarian cancers, and liver cancers, and it prompted the research for other targets and pathways. Its identification in a large proportion of benign demonstrated that this mutation may be a step in melanoma development and prompted further studies [27].

Among the most frequent mutations responsible for oncogenesis in melanoma are observed in the MAPK signaling pathway (mitogen-activated protein kinase). This pathway promotes cell cycle progression, transformation, and cell survival and, in non-cancerous cells, it is activated through cytokine receptors or tyrosine kinase receptors. Ligand binding to the receptors leads to the activation of GTPase switch proteins known as RAS, which in turn activate a series of serine/threonine kinases, which ultimately activate MAPK. Permanently activated MAPK signaling has been observed in almost all melanomas [28].

BRAF is a kinase whose only known activity is in the MAPK pathway and is highly expressed in melanocytes but also hematopoietic tissue and neural cells. The most common BRAF mutation in melanoma is the V600E – a valine to glutamic acid substitution in exon 5, codon 600, a mutation that permanently activates the kinase domain [26]. These mutations are usually found in cutaneous melanoma, specifically in those tumors arising on intermittently sun-exposed skin, despite it not being a typical UV-induced DNA mutation [29].

Other mutations involved in cell proliferation are relatively rare in melanomas, such as mutations that increase RAS activity. They occur mostly in amelanotic nodular subtypes and makeup only about 10-20% of melanomas, with NRAS being the most commonly affected [30]. Interestingly, these two mutations, BRAF and NRAS seldom occur simultaneously in melanomas [31], and in the rare situations when they do, the BRAF mutation is not the typical V600E type [32], suggesting that they have overlapping oncogenic activity and either of them could activate the MAPK pathway.

The above-described mutations can also appear in benign nevi, as well as in melanomas. BRAF mutations can be found in 70-80% of dysplastic nevi [33] and NRAS in congenital nevi [34]. Given these findings, it was at first believed that the BRAF mutation was the initial oncogenic event that triggered all other changes in BRAF-positive melanoma. However, data showed that only 6% of in situ melanomas have a BRAF mutation [26], and that seems to be polyclonal (containing melanocytes with and without the BRAF mutation, or with BRAF wild type), metastatic melanoma tends to be monoclonal [35], suggesting that the mutation might occur later in the oncogenic process. Still, at any moment it occurs, BRAF activation leads to cell growth and dysregulation of the MAPK signaling pathway [36]. Other mutations or alterations can lead to the same result, like overexpression of growth factor receptors like KIT or EGFR (epidermal growth factor receptor)[37,38]. NF1 (neurofibromatosis 1, a tumor suppressor) mutations lead to melanoma proliferation through the MAPK and PI3K pathways [39].

The MTIF gene, responsible for a melanocyte-inducing transcription factor is another essential regulator of melanocyte development, survival, and function, and it can be linked to melanoma development. Its amplification can be found in 15-20% of melanomas, especially metastatic tumors, and it has been shown to contribute, alongside BRAF, to melanoma development [40].

An interesting occurrence in melanoma is the genetic heterogeneity of these tumors, both intralesional and occurring during disease progression. These findings partially explain treatment resistance, on one hand, and can influence therapeutic decisions, on the other [41]. One study investigated both benign and malignant melanocytic lesions and interestingly found that the benign lesions only showed BRAF-V600E mutations [42]. As the disease progressed, more mutations developed. In more advanced lesions, NRAS and subsequently TERT promoter mutations were found. In invasive and advanced melanomas, inactivation of CDKN2A and loss of PTEN and TP53 were observed [41,42]. All these findings suggest that the BRAF-V600E mutation may require other mutations that inhibit tumor suppressors to ultimately lead to melanoma development.

TARGETED THERAPY IN MELANOMAS

The first targeted agent for BRAF V600 was Vemurafenib, which showed significantly higher response rates than the previously used chemotherapeutic agent dacarbazine [43]. Dabrafenib was the second targeted agent to be developed, and despite some side effects such as rash, fatigue, or fever, the therapy was generally well tolerated [44]. Along with a better understanding of the BRAF gene and its interconnected activity with MEK, MEK inhibitors were developed, with trametinib being the first. Simultaneously, studies into BRAF-inhibitor resistance lead to a better understanding of the importance of MEK in the process, and the connection between the two pathways [45]. This eventually led to the association of the two agents, a BRAF inhibitor and a MEK inhibitor, which was studied in a series of clinical trials, for both dabrafenib plus trametinib, as well as for vemurafenib plus cobimetinib, with encouraging results showing a lower rate of cutaneous adverse reactions and increased progress-free survivals [46,47]. This has led to attempts to treat non-BRAF mutated melanoma with a MEK inhibitor in monotherapy, but the results were not promising, suggesting that further genetic studies into the MEK activity and its possible association with other mutations such as NRAS are necessary and could lead to new therapies [43].

Vemurafenib is a selective kinase inhibitor of the MAPK pathway in BRAF-mutated cancer cells, leading to decreased proliferation and apoptosis, while dabrafenib is a reversible, ATP-competitive BRAF inhibitor [48]. Cobimetinib is a non-ATP-competitive inhibitor of MEK1, with a high selectivity for MEK 1 over MEK2. Similarly, trametinib is an allosteric small molecule that binds preferentially to unphosphorylated MEK, preventing Raf-dependent MEK phosphorylation and activation.

In clinical practice, the RT-PCR method is widely used for BRAF mutation detection. The cobas 4800 BRAF V600 kit and the ThxID-BRAF kit have been developed together with the targeted therapeutic agents' vemurafenib and cobimetinib and dabrafenib and trametinib respectively, and are frequently used due to their accessibility, reproducibility and relatively rapid results. These tests use two different primer sets to detect the V600E mutation and the wild-type sequence and then compare the results. While this is sufficient for usual testing, other methods are available for more in-depth analysis and also for rare BRAF types (about 2% of cases), such as Sanger sequencing, pyrosequencing, and high-resolution melt analysis (HRMA)[41].

Systemic therapy for non-mutated melanoma

For decades, melanoma has been considered an incurable disease, especially in later stages, partially because both classic chemotherapy and radiation therapy are not significantly effective, with the drug Dacarbazine showing the best overall response rates of about 10-20% [49]. Research into the development of this malignancy and specific studies on metastatic melanoma has led to the discovery of genetic testing and targeted therapies on one hand, and also to the development of immunotherapies for non-mutated tumors.

There are four main types of immunotherapy: biological agents such as cytokines, interferon, and granulocyte-monocyte colony-stimulating factors; vaccination therapy; adoptive cell therapy and immune checkpoint inhibitors [50]. Biological immunotherapy such as interferons and IL2 were the first alternative to classic chemotherapeutic agents and were frequently used together, to amplify their action. Vaccination therapy is a type of specific immunotherapy that is currently studied. Oncolytic viruses are modified strains of various viruses that maintain their replication capacity but lose their virulence, and such strains have led to cell death in melanoma cell lines in vitro and animal models, by activating antitumoral immunity through the production of cytokines [51]. However, not all types of vaccination are very effective in vivo, such as DNA-based vaccines, despite proving safe and effective in laboratory settings [52]. Adoptive cell therapy is an experimental treatment alternative based on the patient's lymphocytes, which are then activated in vitro and reinjected into the patient to induce an immune response. The technique is time-consuming and elaborate, requiring specialized personnel and equipment [50]. The most effective immunotherapy studied has been the immune checkpoint inhibitors. They are designed to suppress the mechanism of self-regulation in natural immune response and target specific overexpressed molecules in the tumor they are used against. In melanoma, they target PD-1, a cell-surface molecule that downregulates B and T lymphocyte activity (Nivolumab and Pembrolizumab), or CTLA-4, a protein receptor that acts as a negative regulator of T-cell activation (Ipilimumab).

As previously mentioned, most trials for immunotherapy agents have been conducted on regionally advanced and metastatic diseases. Interferon-α has been used for over 20 years before the development of modern therapies to treat advanced disease, with moderate results, as shown in a meta-analysis by Mocellin in 2010 [54], while pegylated IFN-α demonstrated to prolong disease-free survival without improving overall survival in regionally advanced disease [55]. The treatment was associated with significant side effects varying from myalgia, fatigue, fever, headaches, and chills to depression, which could be severe and require treatment [56].

Ipilimumab has been in use since 2015. Its efficacy was demonstrated initially in unresectable metastatic melanoma and subsequently began being used as an adjuvant treatment.

Initial studies proved it increases overall survival in patients who had undergone complete lymph node resection for node metastases (overall survival at 5 years 65.4% compared to 54.4% in the placebo group) but was associated with significant adverse events (in 41.6% of patients)[57], even though these adverse reactions didn't significantly lower quality of life [58]. Ipilimumab is not currently in use as the first line of treatment in regionally advanced or metastatic melanoma.

Nivolumab was approved in 2014 and most studies compared its efficacy with Ipilimumab in the same category of patients, showing a lower rate of recurrence (recurrence-free survival at 18 months of 66.4% vs 52.7% for Ipilimumab and 70.5% vs 63.7% at 24 months) and significantly fewer adverse reactions (17.5% vs 40.4%)[57].

Pembrolizumab was approved in 2019 and showed similar results, disease-free survival of 71.4% vs 53.2% for placebo, and 14.5% moderate to severe adverse reactions vs 3.4% in the placebo group [58].

Combination therapy has proven to be more efficient than monotherapy, the association of Ipilimumab and Nivolumab led to better results in several studies(50), although toxicity may increase, with cutaneous reactions (over 50% of patients), gastrointestinal and thyroid disorders being the most frequent [56].

CURRENT RECOMMENDATIONS IN MELANOMA DIAGNOSIS AND TREATMENT

Any suspicious lesion of the skin should be carefully examined. The surrounding skin should also be checked for satellite lesions and regional lymph nodes should be palpated. Physical examination of the lesion can be completed with dermoscopy by a specialized medical professional for improved accuracy [59]. A patient's personal history of sun exposure, other skin lesions, or cancers is also important, as well as a careful history of the lesion in question. Excisional biopsy with subsequent microscopic examination of suspicious lesions is the only way to accurately establish a melanoma diagnosis. The excisional biopsy should include margins of 1-2 mm around the lesions and into the subcutaneous tissue. Other surgical methods like incisional biopsy are not recommended with very few exceptions and superficial shave biopsies should be avoided because accurate lesion thickness cannot be correctly established [60]. If suspicious palpable masses are identified around the lesion or node basin, further evaluation may be necessary, the most accessible of which is soft-tissue ultrasonography, which can be paired with a fine-needle aspiration.

Once a melanoma diagnosis has been established through biopsy, wide local excision of the scar and surrounding tissue is recommended, the margins of which are established based on Breslow thickness [61]. For in situ melanomas – 0.5 to 1.0 cm; for Breslow < 1.0 mm – 1.0 cm; for Breslow between 1.0 and 2.0 mm – 1.0 to 2.0 cm; and for Breslow > 2.0 mm – 2.0 cm margins are recommended. The histological examination should be performed on permanent sections, given that frozen sections may lead to false negative results [62]. Mohs surgery is also not recommended, with certain exceptions in very superficial tumors located in delicate anatomical sites [61]. Complex reconstruction involving skin flaps should be postponed until microscopic margins are established. Some guidelines accept covering the defect with non-adherent dressing until the final histological result is obtained [61,63].

The spread of malignant cells from the primary tumor occurs primarily through lymphatic vessels to distant sites, through regional lymph nodes. The most valuable predictors for nodal dissemination are Breslow thickness and the presence or absence of ulceration and they are the basis for the indication of a sentinel lymph node biopsy [64]. Thus, all tumors thicker than 1.0mm should be considered for lymph node biopsy. Smaller tumors should be evaluated for poor prognosis factors such as ulceration or microvascular invasion and a decision can be made on that basis [65]. Recent studies have also evaluated the role of complete lymph node dissection in the case of a positive SLN, which was the initial standard of care. They did not demonstrate improved survival and metastasis-free survival in the case of early completion of lymph node dissection, as opposed to monitoring and conducting the procedure in a delayed fashion, when the nodes become identifiable clinically or ultrasonographically [66].

Staging aims to be a simple and practical method to determine a patient's prognosis and guide treatment. It is also helpful in reporting data for future studies and clinical trials. The latest American Joint Committee for Cancer (AJCC) TNM staging system defines separate clinical and pathological staging [20,65]. Clinical staging (cTNM) is based on imaging and clinical examination and pTNM takes into account histological results obtained after surgery. Stage 0 represents melanoma in situ. Stage I is a localized disease, with IA representing tumors of less than 1 mm thickness with or without ulceration (T1a/T1b) or 1-2 mm without ulceration (T2a). Stage II melanoma is also localized, but with larger primary lesions, or ulceration. IIA denotes a 1-2 mm ulcerated lesion, IIB a >2 mm lesion with or without ulceration. Stage III is regional melanoma, with node involvement or satellite or in-transit lesions, with subtypes "a" to "d" for the extent of invasion. It is the subgroup with the most variable 5-year survival rates, ranging from 93% for IIIa to 32% for IIId [68]. Stage IV signifies generalized disease, with distant site dissemination. No subgroups were defined for this stage, given that the overall survival is similar among these patients [50].

Other prognostic factors can have an impact on prognosis. The female gender appears to be associated with a better prognosis, while melanomas of the head and neck are associated with a worse prognosis [69]. Older patients have overall higher mortality [70], nodular and amelanotic melanomas have a worse prognosis [71] while melanoma developed on pre-existing nevi are less aggressive than de novo melanoma [72].

Adjuvant therapy is essential for the outcome of stages III and IV melanoma, the stages with the highest rates of recurrence and dissemination. For earlier stages – stages I and IIA – surgical excision and follow-up seem to be the optimal treatment. For stages, IIB and IIC the risk of adverse reactions is greater than the risk of recurrence, so adjuvant treatments are generally not indicated. For stage III and IV, immunotherapy with Nivolumab or Pembrolizumab, alternatively, if BRAF-V600E genetic test is positive, Dabrafenib and Trametinib is the first-line option [73].

CONCLUSIONS AND FUTURE DIRECTIONS

Diagnosis and treatment of melanoma have evolved greatly to the benefit of patients, especially in later stages, and is even more important as the incidence of melanomas continues to rise. The development of sentinel lymph node biopsy brought major changes to the surgical approach to the disease, and the discovery of the genetic and immune basis of melanoma development changed the treatment protocols that have been used for decades. Classic chemotherapeutic agents are relatively ineffective, recently studied chemotherapy presents more promising results, nonetheless, newer agents also present side effects, sometimes leading to interrupting the treatment, such as colitis and diarrhea for immunotherapy, or keratoacanthoma and squamous-cell carcinoma for targeted therapies [56]. Experimental studies are being conducted with T-cell-based adoptive cell transfer immunotherapy, which proved effective in a laboratory setting [74]. Simultaneously, there is also a need to optimize screening. At the moment, screening and follow-up of low-risk melanomas are based on clinician-led surveillance, but there are proposals to increase patient education on self-examination [75]. Results are yet inconclusive, some studies already show that patients tend to detect melanomas when they are thicker [76], yet the value of self-examination has been proven before [77]. Modern technology is also being researched to aid early diagnosis. Gene profiling can identify low or high risk of developing melanoma [78]. Dermoscopy can be used with computer software to analyze suspicious lesions more efficiently [79]. Finally, the increasing number of smartphone apps focusing on healthcare, including dermatology, should be assessed for accuracy, as many potentially dangerous lesions can go overlooked [80-82].

In conclusion, understanding melanoma has improved spectacularly, which benefits the increasing number of new patients and the therapies developed based on this knowledge changed the death sentence this diagnosis meant until 20 years ago to a manageable condition despite its aggressiveness, keeping in mind altogether that early diagnosis and safe margin excision remain the best and most optimistic course of treatment.

Abstract: *Obesity affects the population worldwide. A hypercaloric diet associated with a sedentary life, stress, and genetic background, triggers various metabolic disorders, such as metabolic syndrome, diabetes mellitus, cancer, cardiovascular diseases, non-alcoholic fatty liver disease, and cognitive impairment. A healthy diet correlated with physical activity, not smoking, and moderate alcohol consumption reduces the risk of developing metabolic diseases. The Mediterranean diet contains antioxidants, fiber, polyunsaturated fats, and compounds with anti-inflammatory, anti-oxidant, anti-cancer, and anti-obesity properties. In a wide variety of species including humans, the reduction of calories between 20-40% significantly improves health, increases longevity, and delays the development of various pathologies. The main aim of this review is to present the comparative effects of the Mediterranean diet versus the hypercaloric diet on insulin sensitivity.*

Keywords: *obesity, diet, MetS, insulin, metaflammation*

INTRODUCTION

Currently, obesity affects the young and adult population worldwide. Hypercaloric diet, sedentary life, and stress lead to obesity [1-3]. Sugar has a well-established metabolic effect. Therefore, the direct pathway includes fructose, which induces lipid and carbohydrate metabolism dysregulation. Indirectly, an excessive sugar intake leads to body weight and fat gain, which further induces the perturbation of lipid and carbohydrate metabolism [4].

A hypercaloric diet triggers dyslipidemia, a key player in the pathogenesis of metabolic diseases [5]. Hyperinsulinemia is installed when insulin secretion is increased, insulin pulses are decreased, and/or hepatic insulin clearance is reduced [6]. This metabolic state is induced by several factors such as the modern Western diet, over-nutrition, and genetic background. Once installed, hyperinsulinemia perturbs the balance of the insulin-growth hormone (GH)-insulin-like growth factor (IGF)-axis and switches to an insulin: GH ratio, leading to lipogenesis and inhibition of lipolysis and further to obesity [6]. In mammals, GH stimulates the production of IGF [7]. The hypothalamus, the pituitary gland, and the liver regulate the GH/IGF-1 system. GH is primarily synthesized by the somatotrophs from the anterior pituitary gland, but reproductive tissues, lymphoid tissues, and the gastrointestinal tract may also syntheses it. Moreover, other endocrine axes may have permissive actions on GH and stimulate IGF-1 expression [8].

Ceramides are lipids from the sphingolipid group, which can act at the plasma membrane, endoplasmic reticulum, and mitochondria levels, being involved in insulin signaling and glucose homeostasis [9]. Under certain metabolic dysregulation (low androgen levels in males and high androgen levels in women) IGF signaling is perturbated leading to metabolic dysfunction and type 2 diabetes [10].

The most common metabolic disorders correlated with hypercaloric diets include metabolic syndrome (MetS) [11,12] diabetes mellitus type 1 and 2 [13], obesity [2,3,14], cardiovascular diseases (CVD)[15], various cancer types [16-

21] infertility, non-alcoholic fatty liver disease (NAFLD) and cognitive impairment [16,22].

HYPERCALORIC DIET AND INSULIN SENSITIVITY

Clinically, insulin resistance (IR) was defined as the incapacity of insulin to increase cellular glucose uptake [23]. Several factors such as age, body weight, genetic predisposition, sedentary life, stress, overstimulation of the sympathetic nervous system, and inflammation may induce the development of IR [24]. Currently, a wide range of populations worldwide have a sedentary life, which correlated with unhealthy diets will conduce to an increased incidence of obesity development related to Diabetes mellitus type 2 [25]. Epigenetic modifications were detected: altered DNA methylation of type 2 diabetes-specific genes such as IRS1, KCNQ1, PPARG, and TCF7L2 [25].

In muscle and liver, IR is correlated with increased circulating levels of free fatty acids, and mitochondrial and endoplasmic dysfunctions [26]. It is well known that type 2 diabetes is installed as a consequence of IR, a process that is frequently associated with obesity. In obesity, hyperglycemia induces excessive insulin production that further conduces to increased beta-cell mass and at the end beta-cell apoptosis. In the last decade, obesity has been named a low-grade inflammatory state, known as metiflammation [27].

In overweight adults, a diet poor in vegetables harms gut microbiota, leading to IR [28].

The muscle, the liver, and the adipose tissue may have increased amounts of ceramide, which is further correlated with IR. The high carbohydrate diet leads to an increased serum level of triglycerides (TG) and decreased levels of HDL-cholesterol, events that are correlated with an increased risk of CVD [25]. Chronic hyperglycemia induces subclinical inflammation, which is the major factor of endothelial damage and represents the link between diabetes and CVD [29].

It is well known that overnutrition conduces to weight gain, which further creates a vicious cycle characterized by IR/hyperinsulinemia. This event will conduce to atherogenic dyslipidemia development, illustrated by hypertriglyceridemia, decreased HDL, and increased LDL [30]. IR affects 25-35 % of the Westernized population [16,22].

Metabolic syndrome (MetS) is defined as a multi-factorial disorder, which received several names such as IR syndrome, metabolic syndrome, Reaven's syndrome, Syndrome X, and the deadly quartet [12,31]. MetS are characterized by abnormal obesity, dyslipidemia, decreased levels of HDL-cholesterol, IR, and hypertension. This metabolic disorder is mainly characterized by obesity and IR. The risk of coronary heart disease and type 2 diabetes is significantly reduced by treating MetS [32].

One of the most common disorders of pregnancy is gestational diabetes mellitus (GDM), which is developed in the second and third trimesters of pregnancy, leading to hyperglycemia of various severity [22,33]. GDM development harms both mother and child, resulting in cesarean delivery, macrosomia, and neonatal hypoglycemia. Moreover, women with GDM have a huge after-pregnancy risk of CVD and type 2 diabetes development [22]. A decreased amount of vegetables and an increase in animal products may cause IR. Pre-pregnancy intake of processed and unprocessed meat is associated with an increased risk of GDM development [34].

Short-chain fatty acids (SCFAs) produced by our gut microbiota can affect the cardiometabolic phenotype because they can enter the systemic circulation and may directly affect the metabolism or the peripheral tissue function [35]. Therefore, SCFAs stimulate the sodium/glucose transporter-1 expression leading to increased absorption of monosaccharides. SCFAs directly influence the host's satiety, because they can promote the glucagon-like peptide-1 (GLP-1) and peptide YY release. This is possible after the interaction of SCFAs with G-proteins expressed by enteroendocrine cells. More than that, SCFAs promote lipogenesis and inhibit fatty acid oxidation, triggering obesity [36].

MEDITERRANEAN DIET AND INSULIN SENSITIVITY

A healthy lifestyle includes a healthy diet, physical activity, not smoking, and moderate consumption of alcohol, especially for women [37]. A vegan diet based only on the consumption of grains, vegetables, and fruits, reduces the risk of MetS, diabetes, and [28, 38], and prevents CVD [39].

A diet rich in fiber, more than 25 g/day in women and more than 38 g/day in men decreases the risk of type 2 diabetes. In addition, a diet that contains nonviscous compounds such as whole grains and insoluble cereal fibers may influence the postprandial glucose response or could be very well fermented by the colon gut microbiota [40]. The results of 30 randomized clinical trials performed on men and women, reported that the consumption of milk and dairy milk products is associated with a decreased activity of insulin and fasting insulin levels [41].

In the case of healthy subjects, an acute endurance exercise in the fasted state causes important changes: stable blood glucose amount, low blood insulin levels, increased lipolysis with an increased blood-free fatty acid concentration, maintenance of the muscular glycogen and high intramyocellular TG oxidation [42].

Recent studies illustrate that replacing the carbohydrates from the diet with fat will decrease fasting TG and will increase the HDL level. Therefore, the results of the meta-analysis that included obese patients who received a high-fat versus low-fat diet, reported after the consumption of a low-fat diet a significantly elevated level of TG and a decreased level of HDL-cholesterol [43].

The Mediterranean diet (MD) consists of antioxidants, fiber, polyunsaturated fats, and compounds with anti-antioxidant, anti-inflammatory, anti-cancer, and anti-obesity properties [44]. Fats intake, especially monounsaturated fat (MUFA) helps the body to reduce the level of insulin. Moreover, 3–4 g of MUFA will decrease the TG levels and blood pressure (BP) in subjects with MetS. Cohort studies reported that a dairy fat consumption of 50% saturated fat leads to a decreased incidence of MetS [43]. A Mediterranean-style diet has positive effects in reducing the MetS prevalence and cardiovascular complications [45]. Even World Health Organisation (WHO) recommends a diet poor in carbohydrates, for adults and children. Their consumption reduces circulating insulin levels and decreases body weight and TG levels [46]. On the other hand, the decreased level of circulating insulin conduces to an increased level of circulating fatty acids, utilized for oxidation and further ketone bodies synthesis. However, this diet has negative effects on the human body in long term [46].

Willems AEM and his research team, published 2021 the results of a meta-analysis regarding the impact of low-carbohydrate and low-fat consumption on markers of MetS in obese patients without cardiometabolic disease [47]. The studies reported that weight loss is the most efficient way to reduce fasting glucose levels independent of macronutrient intake. Moreover, the specific studies reported that carbohydrate and fat intake, but without changing the percentage in the intake of these macronutrients, improved diastolic blood pressure (DPB) and circulating TG levels, without any effect on weight loss [47]. The IR was also improved with both diets, while HDL was only improved in the low-carbohydrate diet. This study concluded that the reduction of carbohydrate and fat intake are not the only factors that improve the MetS markers. This suggests that the guidelines for the prevention of MetS must be re-evaluated [47].

Cellular studies reported that the consumption of polyphenols, such as green tea catechins and epigallocatechin gallates, resveratrol, and curcumin reduce TG accumulation, and stimulate lipolysis and fatty acid-beta oxidation, leading to the reduction of obesity-related inflammation [48].

Ros E and his research team, observe the long-term effects of the MD without any energy restriction on CVD patients [49]. The study reported that MD had good effects on oxidative stress, atherosclerosis, blood pressure, lipids, and inflammation. The consumption of high-unsaturated fat and antioxidant-rich diets such as the MD one may prevent CVD development [49]. Therefore, olive oil, red wine, and nuts have beneficial effects on human health [50]. Dietary polyphenols including fruits, vegetables, whole grains, coffee, tea, and nuts, influence glycemia and type 2 diabetes, by promoting the tissue's glucose uptake, and therefore improving insulin sensitivity [51].

Ryan MC and co-workers conducted a randomized study that included twelve non-diabetic NAFLD patients (6 females/6 males) across 6 weeks. The study participants received MD, rich in MUFA. The study conclusions indicated that MD reduces liver steatosis and improves insulin sensitivity [52]. Abenavoli L and colleagues obtained similar results in NAFLD patients who consumed MD [53].

The clinical study Coronary Diet Intervention conducted by Delgado-Lista J, which enrolled 1,002 coronary patients from Spain, compare the effects of MD rich in virgin oil versus the low-fat diet on the impact of cardiovascular events. At the beginning of the study, 70.6% of the patients had LDL-cholesterol <100 mg/dL, 56.3% of them were obese, 64.4% were former smokers and only 9.6% were active smokers. However, between patients who received MD and a low-fat diet, no difference regarding weight, hypertension, fasting plasma glucose, or lipid profile was observed [54].

The preliminary results of the ongoing trial conducted by Sayón-Orea C regarding the effects of MD and physical activity on 6874 men and women (aged 55 to 75 years) with MetS and no CVD history enrolled between September 2013 and December 2016, illustrated a significant change. The change was visible in BMI, body weight, waist circumference, and lipid profile after 12 months compared with the control group [55].

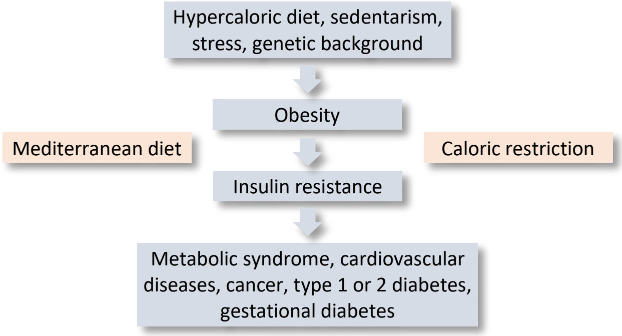
The scientific group of Papadaki reported changes in 18 of 28 MetS components and risk factors [body weight, BMI, waist circumference, SBP, DBP, glucose, insulin, homeostatic model assessment of insulin resistance (HOMA-IR) index, total cholesterol, LDL-cholesterol, HDL-cholesterol, TG, alanine transaminase, hepatic fat mass, C-reactive protein, interleukin-6, tumor necrosis factor-a, and flow-mediated dilatation] and lower risk of CVD incidence, after the consumption of MD [56]. Moreover, low-caloric MD and exercise training are important targets in the treatment of NAFLD [57].

CALORIC RESTRICTION (CR)

CR represents the reduction of kilocalorie (kcal) intakes between 20 - 40%. Therefore, food restriction has been demonstrated to improve health and increase longevity in various groups of species, including humans, dogs, nematodes, rodents, rotifers, and non-human primates. Moreover, CR may delay the development of various pathologies such as autoimmune diseases, CVD, cancer, diabetes, renal diseases, neurodegenerative diseases, and respiratory diseases [58].

The term intermittent fasting (IF) refers to extended periods (16-48 hours) in which people eat little or nothing, alternating with periods of normal food intake. Moreover, periodic fasting (PF) means the periods of fasting or fasting-mimicking performed between 2 to 21 days or more. Studies performed on experimental models (mice and rats) summited on IF and PF, reported a decreased incidence of age-related disorders such as diabetes, CVD, cancer, and neurological disorders [59]. Therefore, a 60% energy restriction 2 days per week, and a five-day diet of 750-1100 kcal for normal and overweight patients conduces to weight loss and improves IR, and reduces the risk of CVD. Thus, IF improves health and counteracts diseases by the activation of several pathways involved in adaptive cellular response, mitochondrial death, autophagy, and DNA repair [59]. Taking into account all the aspects presented, the inflammation generated by obesity can be a key element for the development of oral pathologies such as periodontal disease [60-63]. Depression-related obesity is very dangerous, which may conduce to antidepressants consumptions [64,65].

Figure 1: The relationship between obesity-inducible factors, the Mediterranean diet, caloric restriction, and various metabolic pathologies



Hypercaloric diet, sedentarism, stress, genetic background
Obesity
Mediterranean diet
Caloric restriction
Insulin resistance
Metabolic syndrome, cardiovascular diseases, cancer, type 1 or 2 diabetes, gestational diabetes

CONCLUSIONS

IR is a consequence of many factors such as body weight, stress, genetic predisposition, inflammation, and over-stimulation of the sympathetic nervous system. Hypercaloric diets lead to obesity and IR, pathologies associated with MetS installation, and further CVD development. Healthy diets such as the MD, in combination with weight loss, especially for individuals who are overweight or obese, can drastically improve the cardiometabolic risk factors. MD reduces the level of TG and stimulates lipolysis and fatty acid-beta oxidation. CR, IF and PF improve general health and may delay the development of age-related disorders.

Abstract: *Diabetic foot is one of the main long-term complications of diabetes, having a significant impact on a patient's quality of life. However, prevention by daily checking of the limbs and observance of the rules of care remains particularly important to avoid total or partial amputation. This paper aims to highlight the main challenges and progress in the treatment of the diabetic foot. To achieve this, we analyzed a database consisting of more than 100 articles published in recent years, approaching the treatment of the diabetic foot. The main problems that occur with the diabetic foot are peripheral vascular disease and diabetic neuropathy. These can lead to blisters and skin lesions that can eventually lead to ulcers in the lower limbs and even amputation. In conclusion, prevention is the main method of treatment for diabetic foot, followed by the treatment of each complication depending on when it is identified and its severity.*

Keywords: *diabetic foot; treatment of diabetic ulcers, diabetic foot*

INTRODUCTION

Diabetic foot is one of the most common complications of diabetes, being the leading cause in the world of lower limb amputation [1], as well as frequent hospitalizations in patients with diabetes [2,3]. According to the World Health Organization, diabetic foot syndrome is defined as "ulceration of the foot (distally from the ankle and including the ankle) associated with neuropathy and different grades of ischemia and infection" [4]. The main factors involved in the pathogenesis of diabetic foot ulcers are neuropathy and peripheral vascular disease [5]. However, other factors intervene in the occurrence of diabetes complications such as poor control of blood sugar and blood pressure, dyslipidemia, obesity, smoking, old age, inadequate prevention strategies, and long-term diabetes [5,6]. Considering that there are some limitations of specific treatment, attention remains focused on prevention and foot care education [4]. Careful management of the diabetic foot, which requires a good doctor-patient relationship, is a sure way to prevent amputation and maintain body integrity. Focusing on educating the patient can lead to a better understanding of his pathology, being a very important step in preventing the complications of the disease [5,7]. On the other hand, initiating the most appropriate treatment of complications depending on the stage at which they are discovered is essential in the healing process and even to prevent a possible amputation [3,6,8].

MATERIALS AND METHODS

This review aims to highlight the progress of treatment methods and best strategies providing a quick and correct diagnosis, as well as the complications of the diabetic foot.

We have selected 100 studies in English, German, and Romanian that presented information on methods of treating diabetic foot, difficulties encountered in the differential diagnosis and treatment of diabetic foot, as well as the complications of diabetic foot. Articles presenting the pathophysiology of the diabetic foot were also excluded.

Databases such as PubMed, Up-to-date, Medline, and NCBI were used to perform the search using keywords such as diabetic foot, diabetic foot complications, diabetic foot treatment, differential diagnosis of diabetic foot, and advances in diabetic foot treatment. To select the papers, exclusion criteria were imposed, such as the article publication date should not exceed 20 years old, and the publications to be in English, German, and Romanian treatment protocols were also analyzed.

RESULTS

Diagnostic and differential diagnosis of diabetic neuropathy

Diabetic neuropathy is one of the most common complications of diabetes, with about 50% of patients with type 1 or type 2 diabetes showing symptoms specific to diabetic neuropathy including pain, numbness, tingling, weakness, and difficulties with balance [9]. The most prevalent of diabetic neuropathies is generalized, symmetrical polyneuropathy, in which case may occur sensitive, motor, and autonomic manifestations [10,11].

There is also a high percentage of asymptomatic diabetic peripheral neuropathies, so recognition and prompt intervention are extremely important and reduce the risk of an insensitive foot injury, as well as a possible amputation [8]. Diabetic neuropathy is a diagnosis of exclusion, which is why other possible etiologies must be excluded, given that neuropathy in diabetic patients may have other causes (Table 1) [12]. In addition, some diabetics may have several causes of neuropathy at the same time [10]. The Rochester Diabetic Neuropathy Study reported that nondiabetic peripheral neuropathies were present in about 10% of patients [13].

Table 1: Different diagnoses of diabetic neuropathies [12]

Metabolic disease	Thyroid disease (common) Renal disease
Systemic disease	Systemic vasculities Nonsystemic vasculities Paraproteinemia Amyloidosis
Infectious	HIV, VHB, Lyme
Inflammatory	Chronic inflammatory demyelinating polyradiculoneuropathy
Nutritional	Deficit of B12, post-gastroplasty Pyridoxine, Thiamine, Tocopherol
Industrial agents, drugs, and metal	Industrial agents: Acrylamide, Organophosphorous agents Drugs: Alcohol, Amiodarone, Colchicine, Dapsone, Vinka alkaloids, Platinum, Taxol Metals: Arsenic, Mercury
Hereditary	Hereditary motor, sensory, and autonomic neuropathies

Thus, to optimize outcomes and lead to specific treatment in the diabetic patient, rapid recognition and proper management are essential.

Treatment

When we talk about a diabetic foot, we inevitably think of infection, hospital admission, amputation, and emotional and financial impact [14]. To achieve the best results for a diabetic patient it is necessary to implement a good prevention strategy [15,16]. As we all know, prevention is not always easy, especially for older patients with other comorbidities, but it is essential for a better prognostic and good quality of life [15,17]. The prevention of diabetic neuropathy is based on two goals: good glycemic control and a balanced lifestyle [7,12].

The patient's education is extremely important, in this process it is necessary to present his pathology, the complications that may occur along the way, and simple techniques to follow, such as checking and daily care of the feet, wearing special shoes, signaling any new foot mark and avoiding foot trauma [14,18]. The management of diabetic foot requires a rapid intervention in front of any type of wound, if possible by a multidisciplinary team [16,19]. Daily diabetic foot screening is the best prevention [7,20].

Numerous advances have been made in the management of diabetic foot in recent years, many of which have been applied especially in clinics dedicated to diabetic foot care [14,18]. Most important in the management of diabetic foot is a multidisciplinary team consisting of specialists to act quickly in the face of any type of wound [16,19].

To determine the best treatment method, it is important to determine the severity of the diabetic foot [18]. The treatment can be conservative or surgical [21]. As long as conservative treatment is chosen, it can be performed in an outpatient setting as long as the patient is compliant, the ulceration is superficial and there are no signs of systemic damage [20]. Also, during the treatment period, it is very important to maintain the glycemic values within normal limits and to respect the nutritional regime and the daily exercise program [16,22].

The first step in treating foot ulcer is inspection, to stabilize the degree of damage and the existence or not of the infection, then the wound is cleaned, and if necessary local anesthesia can be performed (many patients have polyneuropathy and no anesthesia is needed) to debridement [23]. In the case of superficial ulcers, a multidisciplinary approach is important to prevent evolution (Table 2) [22].

There is currently a modern local treatment method that involves the use of hydro active dressings, which promote healing through cell proliferation processes in a humid environment. This is done to prevent infection and/or reduce the microbial load, prevent necrosis or eliminate existing ones and adapt to each stage of the wound healing process (cleaning, granulation, and epithelialization) [24].

Table 2: Treatment for superficial uncomplicated foot ulcers [22]

Active ulceration Peripheral neuropathy +/- PAD	**Clinic evaluation**	**Patients evaluation**	**Core**	**Adjuncts**
Non-limb threatening Ulcer	- Superficial - Minimal to no cellulitis - No bone or joint involvement - No significant ischemia - No toxicity	- Reliable - Will conform to treatment - Good support system - Evaluation of comorbidities	- Offloading - Debridement, Dressing - Management of infections - Vascular evaluation if needed - Foot-sparing surgery	- Control blood sugar - Treat comorbidities - Nutrition - Control edema - Physical and emotional therapy
Limb threatening ulcer	Check both feet and legs, and compare Before any intervention, the ulcer probes deeply Note location May involve bone or joint Cellulitis >2cm Lymphangitis, gas, crepitation Ischemia +/-foot pulses, Doppler Systemic toxicity, temperature, white blood cell, lymph nodes Escher, *callor*, granulation tissues	- Unreliable - Poor support systems - Poor control of comorbidities	Therapy - Admit to hospital – complete bed rest - Employ core and adjunct - control blood- stabilize comorbidities - Especially consult (cardiology, renal, infectious disease, etc) - Empirical broad-spectrum antibiotics – adjust by culture and sensitivity - Labs and X-ray Early vascular evaluation and Rx after control of infarction - Foot-sparing surgical vs amputation/revisions - Close follow up	
Septic ulcer	- Same as for limb-threatening ulcer - Be sure to check for undermining deep tissue exposure, abscess, bone, and gas	- Same as limb-threatening ulceration	- Immediate admission – complete bed rest – protect wound and foot, esp heel - Employ core and adjuncts - Intravenous broad-spectrum antibiotics/fluid replacement and resuscitation - Labs and X-rays - Culture and sensitivity – blood culture - Control edema - Emergency aggressive surgical debridement - control all activity infarction, including possible amputations - Stabilizing medically – blood glucose, cardiac(MI, CHF) renal, esp consult (cardiology, renal, ID, etc.) - Evaluate later for antihypertensive, beta-blockers, calcium channel blockers, ACE inhibitors - Early vascular evaluation and Rx after control of infarction - Close follow up	

If the foot ulcer is infected it is especially important to determine if there is a systemic or only local infection [25]. The signs of local infection are erythema, edema, suppuration, and unpleasant odor, but often if the patient has kidney failure they do not show [26].

Depending on the degree of damage and the level of infection, the method of treatment is decided, but the basis of any method of treatment is the initiation of antibiotic therapy and wound care [25].

To choose the best antibiotic therapy, the following criteria are taken into account:

- Local bacterial resistance pattern,
- Proper antibiotic history,
- Gram stains of deep exudate,
- Appearance of wound and pus,
- Associated co-morbid conditions like renal, hepatic, and cardiac impairment [22]

DISCUSSIONS

Clinical aspects and the pathophysiology of diabetic foot

Because there are multiple etiologies underlying this concept, the diabetic foot is considered to be a "syndrome” [27]. It is one of the most common complications of diabetes which in the long-term, if not treated properly, can lead to amputations, disability, and reduced quality of life [4,28]. It is well known that around 25% of diabetic patients will develop a foot ulcer in their lives [28,29]. The pathophysiology of a diabetic foot ulcer is based on triad neuropathy, trauma with secondary infection, and arterial occlusive disease, which appears in various forms [17].

Due to the nerve damage, there is a loss of pain and thermal sensitivity that makes the feet vulnerable to minor injuries caused by excessive pressure, and mechanical or thermal damage [30,31]. Furthermore, motor neuropathy leads to intrinsic muscle atrophy, and foot deformities by altering the biomechanics of the foot, as well as limited joint mobility and postural and coordination deviation [32]. In the end, the formation of calluses comes as an expression of the plantar excessive pressure [28].

One of the goals of treating any ulcer with neuropathy is to reduce weight, regardless of the presence of ischemia [6,33]. Last, the effects of the onset of autonomic neuropathy are diminished sweating, altered blood flow regulation, and microvascular dysfunction, which will lead to dry skin and cracks [21,34]. Repetitive trauma and impaired proprioceptive and exteroceptive sensitivity predispose to skin injury leading to atrophy and dislocation of plantar fat, followed by ulceration and infection [28,35].

There are situations in which, inattention to certain signs (redness, blister formation) or lack of routine foot care, leads to the formation of ulcers and the appearance of infections, undesirable things in diabetic patients with neuropathy, or a history of foot ulcers [3]. Studies have shown that the risk of ulceration increases in diabetic patients with neuropathy, a history of amputations, or foot deformity [16,17].

There are advantages and disadvantages to each kind of wound treatment and multiple solutions for wound dressing are present (Miculickz pomade, 1% silver sulfadiazine cream, zinc hyaluronate solution, bovine collagen, hyperbaric oxygen therapy, hydrocolloid dressing or synthetic skin substitutes)[15,16]. Most of them need real confirmation in randomized studies.

Adjuvant care of diabetic foot ulcers implies systemic factors control of hyperglycemia, control of infection, treatment of vasculopathy (sulodexide, cilostazol) or local factors-peripheral neuropathies, control of pressure at foot level (custom-made ortheses and shoes)[36].

Charcot neuro-osteoarthropathy

Charcot neuro-osteoarthropathy or the Charcot Foot is one of the most severe complications of diabetes [37]. The main factors that lead to this disease are a combination of neuropathy, repeated microtrauma caused by increased weight, and an abnormal bone metabolism leading to inflammatory reactions [35,38]. The result is the destruction of the normal architecture of the foot, subluxation, dislocation, and deformity, most commonly in the ankle and foot [39]. Charcot's Foot is an urgent condition, often associated with ulcers and osteomyelitis, and requires proper management by a foot specialist [40].

Osteomyelitis

Osteomyelitis represents a severe infection involving bone, which occurs due to non-healing ulcers, and if not treated properly may lead to major amputation [27,28]. Two-thirds of the patients with diabetic ulcers may be affected by osteomyelitis, so this complication requires increased attention [38].

In addition, patients with a diabetic ulcers may develop osteomyelitis without any signs of pain, but there may also be a decrease in local signs of infection caused by neuropathy and peripheral arterial disease [41].

CONCLUSIONS

Diabetes mellitus is a chronic disease, characterized by high blood glucose levels [42].

The long-term complications of diabetes are vascular and neurological, and of these, diabetic foot syndrome is one of the most serious consequences in terms of the health complications it generates and the impact on quality of life. It includes ulceration, infection, and osteoarthropathy, known as Charcot's foot. Proper prevention and care of the feet are essential for the early identification of problems and mitigation of consequences. This includes patient education, prophylactic skin, nail care, and proper footwear.

Depending on the severity of the condition, the best method of treatment for the diabetic foot is decided. There are several options, both invasive and non-invasive, for treating this disease.

Abstract: *According to the results of the conducted study there were distinguished the peculiarities of perception of the image of a junior officer by servicemen who participated in hostilities and had various PTSD symptoms. The study included 233 male servicemen with combat experience. The age of the participants varied from 20 to 55 years. It was determined that the image perception of the direct commander by the servicemen who did not have any PTSD symptoms had been influenced by both the key features of the modern way of fighting and the way a protective mechanism of consciousness acted, which gave the possibility to maintain mental health under combat conditions. These servicemen considered the awareness, kindness, and physical strength of their commander to be not important. The first stage was occupied by his/her ability to adequately fulfill his/her leadership function and the power of his/her spirit – the courage and love of the Motherland, which formed his/her reliability. Servicemen who had PTSD symptoms were less satisfied with the role of a junior officer and considered him/her to be less capable of meeting their expectations. They were less interested in commanders who could involve them in situations that required quick, brave action and complete responsibility for the entrusted part of common affairs. The most important factors in the structure of the direct commander image in both studied groups were the power of personality (the ability of self-regulation); however, the servicemen with PTSD symptoms had a specific orientation of these factors – to help their subordinates. They were quite selfishly aimed at using their direct commanders as a way of getting help.*

Keywords: *leader, serviceman, service and combat activity, combat experience, post-traumatic stress disorder, psychological recover*

INTRODUCTION

It was quite difficult to overestimate the role of a junior officer who was a direct commander during the fight. He/she shared with his/her subordinates all the complexities of the service, informed them about orders of senior officers, implemented the coordination of actions of small military groups, made relevant decisions related to the life of the unit, and resolved conflict situations in the team [1]. The behavior of warlords had a deep effect on the mental health of those whom they had to lead [2]. According to Tedeschi and Mcnally, the perception of their leaders influenced not only the way they responded to stressful events, such as hostilities, but also an individual's desire to apply for psychological help in times of personal crisis [3].

The implementation of combat tasks and the preservation of the lives of entrusted him/her servicemen fully depended on the competence of the direct commander's actions under combat conditions. According to Baran and Scott to make a unit's actions effective the subordinates had to trust in the actions of their commander, trust that he would not pose them to the actions with unjustified risk [4]. The research conducted by Sweeney determined that leaders who showed competence before combat actions had a higher level of trust among their subordinates, while those who demonstrated a lack of competence and a lack of previous combat experience could feel distrust from the side of their subordinates [5]. Fisher, et al. [6] received similar conclusions to Sweeney [5] and proposed to add that successful leadership under combat conditions was possible due to previous successes on the battlefield. According to them the experience of participation in hostilities strengthened the leader's confidence and formed appropriate beliefs about self-efficacy.

The experience of joint actions on the battlefield imposed a significant imprint on the perception of the direct commander by his/her subordinates. In particular, the studies conducted by Xue, et al. [7] and Ramchand, et al. [8] proved that servicemen’s perception of their commander (leader) directly related to post-traumatic stress disorder. Other conducted studies (Castro and McGurk; Du Preez, Sundin, Wessely, and Fear; Iversen, Fear, Ehlers, et al.; Jones, Seddon, Fear, et al.; McGurk, Sinclair, Thomas, et al.) also figured out that the perception of the leader by servicemen on the battlefield related to the fair and equal attitude, praise, interest, and concern [9-13]. However, in general, the studies lacked theoretical explanations of the relations which could help to make the image of leadership the only factor that could be changed. The only exception was the study by McGurk, et al. [13] who used the theory of resources conservation that was proposed by Hobfll as an explanation of how positively and negatively leaders could contribute to obtaining or losing the resources, which could explain the connection with PTSD [14].

However, the experienced stressful events could interfere with the acquired combat experience as well as the features and qualities which the serviceman realized in him/herself, his/her comrades, and the commander overcoming life challenges. The negative experience caused by the mental traumatization was painful (Kolesnichenko), having the desire to weaken its power a serviceman could want both to find help and to find the perpetrators [15]. He/she could become isolated, believing that people around him/her could not understand and help. The inability of the serviceman to accept his/her combat experience (Kalesnichenko) [16], and loss of his/her mental health (Kolesnichenko) [17] could have a negative influence on the interaction within the unit, on the perception of the image and the role of the commander (Jansen and Delahaij) [18]. Although the military hierarchy regulated the relations between the leaders and subordinates, unofficially servicemen could abandon their leaders. Such refusal, according to Pierro, Cicero, and Bonaiuto, et al., could cause floats and counterproductive behavior within the military teams [19].

METHOD

Participants and Procedure

The study was conducted in 2022, it was a part of another bigger study related to the determination of important qualities of military leaders. The study included 252 servicemen (42.16% of them were mobilized; 57.84% of them were servicemen under the contract) who participated in hostilities. All the participants were divided following the scale “Mississippi Scale for Combat-Related PTSD” into two groups – group A included the servicemen (155 people) whose PTSD symptoms did not exceed the norm (up to 78 points); group B included the servicemen (97 people) whose indicators exceeded the norm (more than 78 points). This study was based on the presence of definite PTSD symptoms of servicemen who, on request, received qualified individual consulting help from military psychologists and participated in group works aimed at restoring their resilience ability as well as at increasing their ability to accept their own combat experience. It was not about the formed PTSD.

All procedures carried out in the study conformed to the ethical standards of the 1964 Helsinki Declaration and its later amendments. All participants gave consent for their data to be used in this research.

Instruments and Measures

To identify the peculiarities of perception of the ideal representation (image) of a junior officer by the servicemen who participated in hostilities and had PTSD symptoms based on the analysis of modern and foreign studies there were distinguished more than 50 descriptions of the characteristics of military leaders. After the first stage of the Delphi estimation method, where the experts were selected from the military leaders with different ranks, subordinates including those with considerable combat experience, military instructors, and lecturers from the higher military educational establishments. The total number of experts was 65 people. There were made up separate lists of 30 characteristics to evaluate the sergeants, junior and senior officers. It had to be highlighted that the descriptions of the leader’s characteristics in the lists were significantly reduced and edited due to the experts’ recommendations. Due to that definite list of 30 characteristics, which was formed to evaluate the junior officer by the 11-point scale (from 0 to 10 points), the participants who took part in hostilities were asked to evaluate the importance of those characteristics in the "ideal" junior officer, according to their point of view.

To evaluate the degree of PTSD expressiveness of the servicemen who participated in the study there was used "Mississippi Scale for Combat-Related PTSD" [20]. Nowadays, it was one of the most common methods used to measure the signs of PTSD. The scale included 35 statements, each of which can be estimated on a five-point scale. The total indicator which was made up of this method gave the possibility to estimate the degree of influence of the traumatic experience transferred by an individual.

Data Analysis

To represent the data, there was used the main descriptive statistics (arithmetic mean M and standard deviation SD). To compare the estimates provided in the selected groups there was used the T-criteria of the Student. Moreover, there was used the procedure of factor analysis by Principal Components to distinguish the structure of the image of the junior officer due to the given points. Mathematical data was processed with the help of SPSS 17.0.

RESULTS

The points given to the selected groups of servicemen who participated in hostilities were proposed by 30 qualities used to make the perfect image of a junior officer. The points were compared with the help of the T-criterion of the Student. This information was presented in Table 1.

According to Table 1, due to all 30 characteristics which were used to describe the ideal junior officer, the service-men without PTSD symptoms had much higher indicators than the servicemen of the second group. The data indicated not only the presence of different ideas of the representatives of these groups concerning the ideal of a junior commander but also the more negative attitude of the group representatives with PTSD symptoms towards a junior commander in general and towards the role he performed.

It should be noted that both groups had differences between the most important quality and the least important which were minimal. Thus, in the first group, the most important was considered the ability to “adequately informed the subordinates concerning the commanders' orders, pointing out their importance, and could ensure their implementation" (9.16 ± 1.51), and the least important was “own achievements, professionalism and character traits made him/her an attractive model to follow” (8.50 ± 1.97).

In the group with PTSD symptoms, the most important characteristic was "a patriot, who proved by his/her actions his/her love of the Motherland and the ability to protect it" (8.58 ± 1.90), and the least important, as in the first group, was "own achievements, professionalism and character traits made him/her an attractive model to follow” (7.60 ± 2.54). Thus, despite the different evaluation tactics in these groups, the least important were both It should be noted that both groups had differences between the most important quality and the least important which were minimal. Thus, in the first group, the most important was considered the ability to “adequately informed the subordinates concerning the commanders' orders, pointing out their importance, and could ensure their implementation" (9.16 ± 1.51), and the least important was “own achievements, professionalism and character traits made him/her an attractive model to follow” (8.50 ± 1.97).

In the group with PTSD symptoms, the most important characteristic was "a patriot, who proved by his/her actions his/her love of the Motherland and the ability to protect it" (8.58 ± 1.90), and the least important, as in the first group, was "own achievements, professionalism and character traits made him/her an attractive model to follow” (7.60 ± 2.54). Thus, despite the different evaluation tactics in these groups, the least important were both the status and exemplarity of the commander (his/her achievements).

However, if the first group put in the first place a specific function of the leader – the ability to adequately perform the role of intermediate (between the senior commander and subordinates) leader, which ensured the coordination of small units’ actions, the second group valued his/her civil position and his/her own choice – love of the Motherland and the ability to concentrate all strength to protect it; it seemed that only that could justify all the sufferings which they had survived with their commander, under his/her direct guidance.

A lower quantity of points could indicate less satisfaction with the role of junior officers, and their inability to meet expectations. It was necessary to point out that the commander's patriotism was highly appreciated by the representatives of the first group in which he/she, conditionally, occupied the second stage. However, it could be assumed that the servicemen of the first group reflected the protective mechanism on the estimation of the direct commander.

The protective mechanism ensured the preservation of their mental health – the focus on the process of performing their functions under combat conditions – hence occurred a specific view of the role of the commander.

To clarify the assumptions which were made, there occurred a need to look more precisely at the most and the least important qualities of junior officers in both groups. It was inappropriate to consider in detail the whole hierarchy of the characteristics of a junior officer in the distinguished groups due to the minimal differences in the estimations of the most and the least important qualities.

Table 1: The Characteristics of the ideal image of a junior officer in the groups of servicemen with different PTSD signs (in standard points)

№	Variable	Studied		$t_{кр}$	p
		group A	group B		
1	He/she worried about the welfare of his/her subordinates and found opportunities to organize the most convenient conditions for their service in the current circumstances	9.02±1.77	8.14±2.43	3.09	.01
2	He/she was brave and strong-willed, and with his/her example he/she inspired the subordinates to overcome difficulties	9.08±1.54	8.14±2.49	3.33	.01
3	He/she was able to take any situation under his/her control, to make up-to-date decisions	9.03±1.68	8.24±2.44	2.79	.01
4	He/she was reliable, did not give up, and acted effectively even having minimal resources	8.96±1.67	8.10±2.31	3.16	.01
5	He/she saw the prospects that his/her unit had and could unite the subordinates to achieve these prospects	9.01±1.63	8.06±2.46	3.36	.01
6	His/her achievements, professionalism, and character traits made him/her an attractive model to follow	8.50±1.97	7.60±2.54	2.96	.01
7	He/she adequately informed the subordinates concerning the commanders' orders, pointing out their importance, and could ensure their implementation	9.16±1.51	8.31±2.34	3.17	.01
8	He/she had good communication skills and could adequately resolve conflict situations	9.04±1.62	8.46±2.23	2.21	.05
9	He/she could explain, teach, and help to form the necessary skills as well as the traits of character	8.92±1.67	8.00±2.34	3.34	.001
10	He/she was aware, well-informed, and could easily acquire the necessary knowledge as well as professional experience	8.84±1.76	7.91±2.39	3.31	.001
11	He/she could form the team – everyone in the unit was "in his/her place" both due to professional skills as well as due to personal traits, which ensured his/her effective work	9.05±1.62	8.03±2.37	3.72	.001
12	He/she formed confidence in the better future that which individual wanted to follow with his/her brethren	8.83±1.62	8.00±2.22	3.15	.01
13	He/she was confident in him/herself, in his/her decisions, and in the unit itself – he/she did not allow any doubts, uncertainty, and apathy which could undermine the efficiency of the unit activity	9.01±1.61	8.13±2.26	3.33	.001
14	He/she adequately evaluated the importance of solving certain problems. To solve them he/she showed the appropriateness of persistence, honesty, and stubbornness	9.04±1.52	8.25±2.06	3.25	.01
15	He/she was quite independent – made up-to-date decisions and took responsibility for the given orders	8.95±1.78	7.90±2.33	3.82	.001
16	He/she was friendly and available for the subordinates to communicate, they could share their problems as well as their doubts. He/she was also available for their families who were concerned about the lives of their loved ones	8.82±1.78	8.22±2.13	2.30	.05
17	He/she was emotionally balanced and stress-resistant and could control his/her negative experience	8.97±1.62	8.29±1.96	2.84	.01
18	His/her morality, belief perseverance, and ability to defend those beliefs gave him/her the possibility to be a role model for his/her subordinates	8.89±1.60	8.17±2.08	2.92	.01
19	He/she was demanding to others as well as to him/herself and inspired the others to imitate him/her by own self-discipline	8.98±1.47	8.10±2.23	3.42	.001
20	He/she was tactful being demanding to his/her subordinates and taking care of them. He/she represented respect and maintained a sense of dignity in his/her subordinates	8.91±1.66	8.16±2.17	2.91	.01
21	He/she was able to quickly and adequately evaluate the professional situation and its changes, to make necessary decisions for the normalization of the situation	9.08±1.51	8.17±2.29	3.48	.001
22	He/she formed the feeling of "we" in servicemen: "We are defenders", "If not we, then who?"	9.03±1.64	8.22±2.30	2.99	.01
23	He/she carefully considered his/her decisions, calculated all the possible complications within the process of their implementation	8.98±1.69	8.23±2.16	2.90	.01
24	He/she formulated his/her opinion, gave consistent orders, and agreed with other executives	9.05±1.49	8.42±2.06	2.63	.01
25	He/she maintained good physical form, could bear the hardness of work on par with everybody in the unit if it was necessary, he/she could take on the professional functions of any of the subordinates	8.76±1.77	8.27±2.15	1.87	.1
26	He/she could take on full responsibility for the actions of his/her subordinates	8.96±1.68	8.29±2.26	2.51	.05
27	He/she ensured the information security of his/her unit, did not allow the leakage of information related to the servicemen and their families	9.05±1.64	8.50±1.97	2.29	.05
28	He/she was a patriot, who proved by his/her actions his/her love of the Motherland and the ability to protect it	9.12±1.77	8.58±1.90	2.22	.05

29	He/she could adequately evaluate the physical and psychological state of his/her subordinates, could organize the necessary help for them	9.11±1.50	8.40±2.09	2.92	.01
30	He/she was professional – had good professional knowledge, skills, and experience in their implementation under combat conditions	9.05±1.70	8.44±2.20	2.33	.05

There was a need to highlight that such minimality of differences of estimations of the most and the least important characteristics of the direct commander in both studied groups of the participants in hostilities testified the syncretic (fusion) of the perception of his/her image, as a significant individual in the life of a serviceman, while surviving under combat conditions directly depended on him/her.

In the first group, the most important (those who occupied leading positions and ranks in the hierarchy) were the following qualities:

1) adequately informed the subordinates concerning the commanders' orders, pointing out their importance, and could ensure their implementation (9.16 ± 1.51);

2) a patriot, who proved by his/her actions his/her love of the Motherland and the ability to protect it (9.12 ± 1.77);

3) could adequately evaluate the physical and psychological state of his/her subordinates, could organize the necessary help for them (9.11 ± 1.50);

4) able to quickly and adequately evaluate the professional situation and its changes, to make necessary decisions for the normalization of the situation (9.08 ± 1.51);

5) brave and strong-willed, with his/her example he/she inspired the subordinates to overcome difficulties (9.08 ± 1.54).

Conditionally the least important in the first group (those who occupied the least leading positions and ranks in the hierarchy) were the following qualities:

1) own achievements, professionalism, and character traits made him/her an attractive model to follow (8.50 ± 1.97);

2) maintained good physical form, could bear the hardness of work on par with everybody in the unit, if it was necessary, he/she could take on the professional functions of any of the subordinates (8.76 ± 1.77);

3) friendly and available for the subordinates to communicate, they could share their problems as well as their doubts. He/she was also available for their families who were concerned about the lives of their loved ones (8.82 ± 1.78);

4) formed confidence in the better future that which individual wanted to follow with his/her brethren (8.83 ± 1.62);

5) aware, well-informed, and could easily acquire necessary knowledge as well as professional experience (8.84 ± 1.76).

As could be seen, it was not so important for servicemen, who retained their mental health throughout the fight, which achievements their direct commander had, and whether he was well-informed, friendly, and strong. Among all the personal traits, only his/her patriotism and courage were important. For these servicemen, the first place was occupied by his/her ability to adequately fulfill his/her leadership functions – to set the combat tasks with adequate consideration of the combat situation and the subordinates he/she had.

In the group that had PTSD symptoms, the following characteristics received the highest points:

1) a patriot, who proved by his/her actions his/her love of the Motherland and the ability to protect it (8.58 ± 1.90);

2) ensured the information security of his/her unit, did not allow the leakage of information related to the servicemen and their families (8.50 ± 1.97);

3) had good communication skills and could adequately resolve conflict situations (8.46 ± 2.23);

4) professional – had good professional knowledge, skills, and experience in their implementation under combat conditions (8.44 ± 2.20);

5) formulated his/her opinion, gave consistent orders, and agreed with other executives (8.42 ± 2.06).

The participants of hostilities who had PTSD symptoms considered the following characteristics to be the least important for junior officers:

1) own achievements, professionalism, and character traits made him/her an attractive model to follow (7.60 ± 2.54);

2) quite independent – made up-to-date decisions and took responsibility for the given orders (7.90 ± 2.33);

3) aware, well-informed and could easily acquire necessary knowledge as well as professional experience (7.91 ± 2.39);

4) could explain, teach, and help to form the necessary skills as well as the traits of character (8.00 ± 2.34);

5) formed confidence in the better future that which individual wanted to follow with his/her brethren (8.00 ± 2.22).

For the servicemen of the second group as well as for the first one the achievements of their commander and his/her awareness were not important. Moreover, they did not believe that he/she could bring them to a better future, or help them to overcome their problems related to their personal life (to form the necessary traits). It seemed that those psychologically injured servicemen transferred to the image of the direct commander their confidence that their lives had no prospects, and no one could help them (one of the PTSD signs) neither due to their initiative (due to the love to their relatives) nor due to their functional responsibilities.

However, among the most important characteristics of the direct commander, three out of five in their formulation in one way or another indicated their ability to protect their subordinates. The other two were related to the cognitive functions which, among other things, were able to ensure the definite success of servicemen who, due to the loss of mental health, had problems with attention and order understanding. Thus, the attitude towards the direct commander by the servicemen who had PTSD symptoms showed opposite tendencies – on the one hand, they sought protection and help to keep the success in performing the given tasks and not lose the remains of self-esteem, on the other hand – they did not believe the fact that their direct commanders themselves or by the order of senior officers could help them to cope with their negative experience, and could direct them to the path leading to the "better future." The negativity of their estimations related to junior officers was caused by internal contradictions concerning their attitude towards them, the attitude which combined the search for protection and helping with the despair in the fact that they could help them (such PTSD characteristics as the belief in the uniqueness of their traumatic experience and the unpromising life).

Moreover, there were several characteristics in the process of their estimation in two groups, there had been distinguished the highest differences (more than 10 positions/ranks).

Thus, the servicemen whose PTSD symptoms did not exceed the norm, higher positions were occupied with the following characteristics:

- able to quickly and adequately evaluate the professional situation and its changes, to make necessary decisions for the normalization of the situation (4th position in contrast to 16.5th position in the second group);

- brave and strong-willed, with his/her example he/she inspired the subordinates to overcome difficulties (5th position in contrast to 19th position in the second group);

- could form the team – everyone in the unit was "in his/her place" both due to professional skills as well as due to personal traits, which ensured his/her effective work (7.5th position in contrast to the 25th position in the second group).

Instead, in the second group, higher positions were occupied with the following characteristics:

- could take on full responsibility for the actions of his/her subordinates (8.5th position in contrast to 20.5th in the first group);

- emotionally balanced and stress-resistant, and could control his/her negative experience (8.5th position in contrast to 19th in the first group);

- maintained good physical form, could bear the hardness of work on par with everybody in the unit, if it was necessary, he/she could take on the professional functions of any of the subordinates (10th position in contrast to 29th in the first group);

- friendly and available for the subordinates to communicate, they could share their problems as well as their doubts. He/she was also available for their families who were concerned about the lives of their loved ones (14th position in contrast to 28th in the first group).

This data could indicate that servicemen with PTSD symptoms were less interested in commanders who could involve them in situations that required quick, brave actions, and complete responsibility for the entrusted part of the common affairs; instead, they required a commander who could take on the responsibility for their failures as well as a part of their direct responsibilities, and at the same time he/she would not condemn (express any negative attitude).

There was a need to consider the structure of characteristics of junior officers formed with the help of a factor analysis due to the estimations made by the servicemen from the selected groups.

In the group of servicemen, where the indicators of PTSD symptoms did not exceed the norm, after the simplification procedure, there was formed a three-factors structure (see Table 2), described 78.47% of the symptoms' dispersion. This structure was presented in Table 2.

The content of the first and the most important factor (40.56%) was determined with the following variables "emotionally balanced and stress-resistant, and could control his/her negative experience" (0.815), "able to quickly and adequately evaluate the professional situation and its changes, to make necessary decisions for the normalization of the situation"(0.771), "maintained good physical form, could bear the hardness of work on par with everybody in the unit, if it was necessary, he/she could take on the professional functions of any of the subordinates"(0.771), "confident in him/herself, in his/her decisions and in the unit itself – he/she did not allow any doubts, uncertainty, and the apathy which could undermine the efficiency of the unit activity"(0.743), and "demanding to others as well as to him/herself, and inspired the others to imitate him/her by own self-discipline" (0.663). This factor was interpreted as the power of "I" and as the power of personality based on a developed ability to self-regulation.

The second factor (23.05%) was determined by the variables such as "had good communication skills and could adequately resolve conflict situations" (0.796) and "adequately informed the subordinates concerning the commanders' orders, pointing out their importance, and could ensure their implementation" (0.781). This factor could be marked as professional communicative competence, which showed up, both in the ability to formulate a combat mission and convey information as well as in the ability to resolve the conflict.

Table 2: The structure of the characteristics of junior officers formed following the estimations made by servicemen who did not have clearly expressed signs of PTSD (in standard points).

Variable	Factors		
	1	2	3
He/she adequately informed the subordinates concerning the commanders' orders, pointing out their importance, and could ensure their implementation	0.275	0.781	0.235
He/she had good communication skills and could adequately resolve conflict situations	0.343	0.796	0.208
He/she was confident in him/herself, in his/her decisions, and in the unit itself – he/she did not allow any doubts, uncertainty, and apathy which could undermine the efficiency of the unit activity	0.743	0.273	0.435
He/she was emotionally balanced and stress-resistant and could control his/her negative experience	0.815	0.359	0.139
He/she was demanding to others as well as to him/herself and inspired the others to imitate him/her by own self-discipline	0.663	0.234	0.291
He/she was able to quickly and adequately evaluate the professional situation and its changes, to make necessary decisions for the normalization of the situation	0.794	0.342	0.186
He/she maintained good physical form, could bear the hardness of work on par with everybody in the unit if it was necessary, he/she could take on the professional functions of any of the subordinates	0.771	0.259	0.302
He/she was professional – had good professional knowledge, skills, and experience in their implementation under combat condition	0.413	0.397	0.819

The third factor was completely correlated with the variable "was professional – had good professional knowledge, skills, and experience in their implementation under combat conditions" (0,819). Some clarifications of the content of this factor were made by a variable "was confident in him/herself, in his/her decisions and in the unit itself – he/she did not allow any doubts, uncertainty, and apathy which could undermine the efficiency of the unit activity" (0.435), which emphasized the active energetic position of the servicemen who had professional knowledge and experience. Accordingly, this factor was marked as professional efficiency – the ability to act effectively based on professional knowledge and experience.

For the servicemen who had expressed PTSD symptoms, the structure of the characteristics of junior officers was simpler and had only 2 factors, which described 79.88% of the signs' dispersion. This structure was presented in Table 3.

The content of the first factor (59.55%) was defined with the following variables "clearly saw the prospects that his/her unit had and could unite the subordinates to achieve these prospects" (0.887), "was brave and strong-willed, with his/her personal example he/she inspired the subordinates to overcome difficulties"(0.877), "was reliable, did not give up, acted effectively even having minimal resources" (0.859), "was professional – had good professional knowledge, skills, and experience in their implementation under combat conditions" (0.844), "adequately evaluated the importance of solving certain problems. To solve them he/she showed the appropriateness of persistence, honesty, and stubbornness" (0.837), "own achievements, professionalism and character traits made him/her an attractive model to follow" (0.832), "was able to take any situation under his/her control, to make up-to-date decisions"(0.827), "was confident in him/herself, in his/her decisions and in the unit itself – he/she did not allow any doubts, uncertainty, and apathy which could undermine the efficiency of the unit activity" (0.815), "adequately brings to subordinates leadership, their importance, capable of ensuring their implementation adequately informed the subordinates concerning the commanders' orders, pointing out their importance, and could ensure their implementation" (0.805), and "worried about the welfare of his/her subordinates and found opportunities to organize the most convenient conditions for their service in the current circumstances" (0.761). This factor had a weight that exceeded the weight of the second factor and combined the variables, the vast majority of which described the ability of a junior officer to self-regulation, but unlike the situation in the first group, this variable received a specific direction – to ensure a prospective development and well-being of their subordinates.

The second factor (20.33%) was determined by two variables – "was friendly and available for the subordinates to communicate, they could share their problems as well as their doubts. He/she was also available for their families who were concerned about the lives of their loved ones" (0.885) and "was emotionally balanced and stress-resistant, and could control his/her negative experience" (0.847). Those were the variables that occupied much higher positions (ranks) in servicemen with the signs of PTSD than in the servicemen of the first group which were already marked as a tendency not to condemn their subordinates but to help them.

Table 3: The structure of the characteristics of junior officers was formed following the estimations made by servicemen who had expressed PTSD symptoms (in standard points).

Variables	Factors	
	1	2
He/she worried about the welfare of his/her subordinates and found opportunities to organize the most convenient conditions for their service in the current circumstances	0.761	0.363
He/she was brave and strong-willed, and with his/her example he/she inspired the subordinates to overcome difficulties	0.877	0.238
He/she was able to take any situation under his/her control, to make up-to-date decisions	0.827	0.296
He/she was reliable, did not give up, and acted effectively even having minimal resources	0.859	0.209
He/she saw the prospects that his/her unit had and could unite the subordinates to achieve these prospects	0.887	0.254
His/her achievements, professionalism, and character traits made him/her an attractive model to follow	0.832	0.332
He/she adequately informed the subordinates concerning the commanders' orders, pointing out their importance, and could ensure their implementation	0.805	0.305
He/she was confident in him/herself, in his/her decisions, and in the unit itself – he/she did not allow any doubts, uncertainty, and apathy which could undermine the efficiency of the unit activity	0.815	0.369
He/she adequately evaluated the importance of solving certain problems. To solve them he/she showed the appropriateness of persistence, honesty, and stubbornness	0.837	0.360
He/she was friendly and available for the subordinates to communicate, they could share their problems as well as their doubts. He/she was also available for their families who were concerned about the lives of their loved ones	0.272	0.885
He/she was emotionally balanced and stress-resistant and could control his/her negative experience	0.310	0.847
He/she was professional – had good professional knowledge, skills, and experience in their implementation under combat conditions	0.844	0.294

As it could be seen, the structure of the characteristics of a junior officer within the servicemen who had the expressed PTSD symptoms had some similarity with the structure given by the first group, it also referred to the power of personality (ability to self-regulation) and definite communicative competence; however, the mentioned factors had a specific orientation in this group – to help his/her subordinates. They were quite selfishly aimed at the use of their direct commanders to help them, their structure "omitted" professional efficiency, achievement of professionally important goals, and so on.

DISCUSSIONS

Although the study conducted by Sheerin C.M., et al. [21] which used a more abstract research plan did not reveal any connections between PTSD and negative attitude towards the world in general, the study was conducted gave the possibility to suggest that having expressed PTSD symptoms the people around were perceived more negatively (at least those who were responsible for the lives of a serviceman – their direct commanders).

In the study by Bartholomew, et al. it was determined that servicemen who had signs of PTSD were less focused on their future [22]. In particular, the servicemen who had the signs of PTSD had disbelief in the achievement of a better future which extended to others, to those who had to direct the achievements of this better future to the whole team – to the direct commander.

It was interesting that real and perceived social support, as a factor that affected stress overcoming, had been already studied earlier, for example, it was discussed in works by Smith, Benight, and Cieslak [23]. An interesting phenomenon was identified in the study which was related to internal conflict attitude towards an individual the one who had to help, who was responsible for that morally and formally – that individual was a direct commander. He was perceived both as the one whom they expected to get help from and as the one whose real ability to help they had poorly trusted.

Caska-Wallace et al. worked with the negative changes in servicemen who were under PTSD influence [24]. They determined that the increase in problems in relationships between veterans and their partners referred to effective communication as well as communication related to the address of problems' solutions. The results of the conducted research suggested that not only a partner, but also a commander, and probably another significant person who surrounded a serviceman with PTSD symptoms, was taken as one who had to help, to solve the problems of psychologically traumatized servicemen, however, he/she could not solve those problems. That became a reason for the conflicting attitude of the serviceman towards definite surroundings.

Moreover, it had to be noted that if this study of an individual, who did not have signs of PTSD in the structure of the commander image, distinguished his/her strong personality and the ability to self-regulation as leading factors, the research by Rahman, et al. figured out that the perception of self-efficacy was a kind of traumatic stress prevention [25]. Conducting a certain analogy, it could be assumed (even if that required further studies) that the perception of the figure of the commander, as self-effective and capable of self-regulation was a kind of prevention of PTSD formation in his/her subordinates in the future. The procedure of study did not give any possibility to suggest whether the perception of the commander as an effective one was the prevention of PTSD symptoms in subordinates, or whether the absence of signs of PTSD reduced the negativity in the perception of the commander's figure, of his/her self-efficacy, of his/her "I", or of the experience became a reason for the posttraumatic growth and perception of oneself and of the one who ran the process of overcoming the life troubles, as those which had a significant individual power (Tedeschi and Calhoun) [26]. Also, the format of the study did not give the possibility to reveal whether the presence of PTSD symptoms caused the situation that servicemen were less interested in the commander who could involve them in dangerous swift-fleeting conditions, or whether servicemen who avoided danger lost their opportunities for productivity and growth following the study by Jamieson, et al. [27].

Unfortunately, the study did not give any possibility to identify cause-effect relationships, it did not give the possibility to determine whether PTSD symptoms had an influence on the image of the military leader, or whether the attitude towards the commander became one of the reasons for acquiring PTSD symptoms during the fight. Thus, the determination of those relationships would be the purpose of the feather studies.

CONCLUSIONS

Thus, the conducted study showed that the existing extreme experience of participating in hostilities led to the syncretic perception of the image of the junior commander – all qualities were perceived as extremely important.

In servicemen who did not have signs of PTSD (able to accept their combat experience as well as experience of interaction under combat conditions), the perception of the direct commander image had been influenced both by the peculiarities of the modern way of battle conduction (the actions made by small groups which were coordinated by the leader – that was where significant importance of the ability to adequately inform about the leaders' orders and to implement the role of a coordinator came from) and by the action of a protective mechanism of consciousness, which gave the possibility to maintain mental health under combat conditions, so-called focus on the process of performing their combat tasks.

For these servicemen, the awareness, kindness, and physical strength of their commander were less important. His/her ability to adequately fulfill his/her leadership function (pose combat tasks with adequate consideration of the combat situation and his/her subordinate forces) and the power of his/her spirit including the courage and love of the Motherland, which formed his/her reliability (gave the possibility to perform the combat tasks under extreme conditions and not to give those tasks up).

The servicemen with expressed PTSD symptoms were less satisfied with the role of a junior officer. They considered him/her less capable of meeting their expectations. They were less interested in commanders who could involve them in situations that required quick, brave action and complete responsibility for the entrusted part of the common affair, they required more the commander who would take care of them. Moreover, that commander would not blame the subordinates for their failures, but also, he/she would take on a part of their professional duties and responsibilities for their activity and inactivity.

In the servicemen with expressed PTSD symptoms the negativism of the attitude towards the role of the direct commander was caused by internal contradictions – on the one hand, they looked for the commander who could protect and help, on the other hand – they did not believe that he/she could help them, considering their experience to be unique, which was not appropriate for knowledge and experience of overcoming others.

In the structure of the direct commander image in both studied groups the most important factor was the power of personality (ability to self-regulation), however, in the servicemen with the expressed PTSD symptoms, these factors had specific orientation – to help their subordinates. They were quite selfishly aimed at using their direct commanders to help them.

REVIEW

The Role of Vitamin D in the Development and Progression of Osteoarthritis

Symeon Naoum[1]

Correspondence: Symeon Naoum, naoumsimeon@gmail.com

Abstract: *Low levels of vitamin D in patients with osteoarthritis (OA) rather adversely affect the structure and function of articular cartilage. Low levels of vitamin D are also associated with joint pain, limited physical activity, quality of life, as well as decreased muscle strength, primarily in the lower extremities with adverse OA progression. A high percentage of low vitamin D levels was found in patients with OA and joint arthroplasty as well as a less satisfactory postoperative follow-up in patients with low vitamin D levels. The administration of vitamin D supplementation in patients with knee osteoarthritis has been associated with improved articular cartilage architecture, and reduced joint pain, combined with improved functionality and quality of life in patients with OA.*

Keywords: *arthroplasty; vitamin D; osteoarthritis; vitamin D supplementation; vitamin D receptors*

INTRODUCTION

Osteoarthritis (OA) is defined as a heterogeneous group of conditions, leading to symptoms and signs associated with a disorder of joint cartilage, as well as with lesions of the subchondral bone and joint boundaries [1-3]. It is distinguished into primary OA when it cannot be attributed to a distinct pathological disease and secondary OA when it is related to other conditions such as injury, congenital bone disease, metabolic diseases, crystal deposition disease, or neuropathic arthropathy (Charcot's joint) [4-6]. In this review, we will only deal with the primary OA.

Regarding the role of vitamin D in OA development and progression, we will deal with the following important fields based on information from the PubMed database we searched for using the keywords osteoarthritis, vitamin D, vitamin D receptor, vitamin D supplement, joint replacement, until October 30, 2019:

1. Correlation of OA development with genetic polymorphisms of vitamin D receptor.
2. Effect of vitamin D on the structure and function of articular cartilage.
3. Correlation of low levels of vitamin D with the risk of OA development and progression.
4. Effect of vitamin D on OA clinical manifestations.
5. Correlation of vitamin D levels with muscle strength in patients with OA.
6. Correlation of vitamin D levels with the risk of arthroplasty and postoperative progress of OA patients' joints.
7. The role of vitamin D supplementation in patients with OA.

Before referring to the above, it should be noted that desired levels of vitamin D [as estimated by measuring the levels of 25-hydroxyvitamin D [25(OH)D] are >30 ng/mL. Levels <10 ng/mL mean insufficiency, while 10-30 ng/mL consist of a level lower than the considered optimal amount of vitamin D. In 2011 the Institute of Medicine (IOM) defined as insufficiency when the of 25(OH)D level was <20 ng/mL [7], while the Endocrine Society (ES) when the levels were at 20-29 ng/mL [8].

It should also be noted that vitamin D has a significant effect on the immune system function, as it inhibits the synthesis and action of prostaglandins, activates monocytes and macrophages, and has an inhibitory effect on the maturation and function of antigen-presenting progenitor cells and production of inflammatory cytokines such as interleukin-1 (IL-1), interleukin-6 (IL-6) and interleukin-8 (IL-8), etc [9-13]. Vitamin D deficiency in individuals with a genetic predisposition may affect the immune system's response and tolerance process by affecting T lymphocytes and B lymphocyte function [12,13].

CORRELATION OF OA DEVELOPMENT WITH GENETIC POLYMORPHISMS OF VITAMIN D RECEPTOR

The possible correlation between gene polymorphisms that encode the synthesis of the vitamin D receptor (VDR) and the risk of developing OA has been studied. However, the conclusions of those studies are contradictory. In a meta-analysis, it was reported that the active metabolite of vitamin D, 1,25(OH)2D3 binds to its receptors in the articular cartilage and may lead to hypertrophy and impairment of chondrocyte function [14]. A study found an association between the risk of OA of the hand extremities with polymorphisms of the vitamin D receptor [15], while another study in postmenopausal women with OA of the knee, it was found a correlation between this risk and a TaqI polymorphism of vitamin D receptor [16]. On the other hand, in another meta-analysis of 10 studies, no association was found between TaqI, BsmI, and ApaI polymorphisms and the risk of developing OA in the knees, hips, hands, and lumbar spine [17]. In the meta-analysis of Z.-H. Zhu et al., a weak association of ApaI polymorphism with the risk of developing OA in Asian (but not in European) patients with OA were found [18]. No correlation between vitamin D receptor polymorphisms and the risk of developing OA in the knees was found in the meta-analysis of Rodriguez-Fontenla et al. in 9 Genome-wide studies [19] as well as in other studies [20,21]. Another interesting study carried out by Hansen AK et al. found that 25(OH)D3 and 1,25(OH)2D3 led to an increase of chondrocytes proliferation, in combination with a reduction of proteoglycans synthesis, and thus with a reduction of the intercellular substance [22].

EFFECT OF VITAMIN D ON ARTICULAR CARTILAGE STRUCTURE AND FUNCTION

In male Sprague-Dawley rats, Pascual-Garrido et al. used Micro-CT analysis to detect adverse effects of vitamin D deficiency on articular cartilage. Of particular importance is Jiang X et al.’s study in rats, in which it was found that vitamin D promotes function, the differentiation of the bone marrow-derived mesenchymal stem cells (BMSCs) in mature chondrocytes, enhanced by the action of transforming growth factor-β1 (TGF-β1) and their migration to the articular cartilage [24].

Low levels of vitamin D in OA patients have been shown to adversely affect the structure and function of articular cartilage. In a study in which patients with knee OA participated, low levels of vitamin D were found to be associated with loss of knee articular cartilage as assessed by the decreased joint space [odds ratio-OR=2.3 (Cl, 0.9-5.5)] and the increased size of the osteophytes [OR=3.1 (Cl, 1,3-7,5)] [25]. Ding et al. randomly selected patients (aged 51-79 years, 50% women) in whom the volume of articular cartilage, the presence of articular cartilage deficits in knees using X-rays and magnetic resonance imaging (MRI), as well as the 25(OH)D levels, were assessed at the beginning. 2.9 years later in 353 of these individuals, a correlation between low levels of 25(OH)D and articular cartilage loss was found [26].

In a study in 2014, 80 patients were classified according to 25(OH)D levels into three groups (<10, 10-20, and ≥20 ng/mL). It was found that vitamin D deficiency (<10 ng/mL) may significantly affect the articular cartilage thickness of the peripheral part of the femur (lateral femoral condyle of the right knee and the medial femoral condyle of the left knee) as found by ultrasound [27].

Moreover, in Zheng S et al. study of 340 patients with knee OA, the results showed a correlation between low levels of 25(OH)D with the decreased knee articular cartilage volume, as well as the presence of articular cartilage deficits, bone marrow damage and an increase of synovial membrane thickness (a finding compatible with inflammation) as assessed by MRI [28].

Lastly, in another study of 340 patients with symptomatic OA of the knee and vitamin D deficiency, 25(OH)D levels were measured at the start of the study as well as 3 and 24 months later. It was found that patients with stable normal levels of vitamin D compared to patients with low levels (25(OH)D >50 nmol/L vs ≤50 nmol/L) had a lower loss of joint cartilage volume, thinner synovial membrane and less articular fluid collection [28].

Low levels of vitamin D have also been linked to increased levels of cytokines involved in inflammation in patients with OA. A study by Askari A et al. in 131 patients with OA who compared 262 healthy controls found that lower vitamin D levels were associated with higher levels of interleukin 17A (IL-17A) and interleukin 23 (IL-23), cytokines that promote inflammation in patients with OA [29].

CORRELATION OF VITAMIN D LOW LEVELS WITH THE RISK OF OA DEVELOPMENT AND PROGRESSION

Several studies have focused on the possibility and to what extent low levels of vitamin D in OA patients are associated compared to individuals of the same sex and similar age in the general population and OA progression, with the results being controversial. In Bergink AP et al. meta-analysis, no significant correlation was found between vitamin D levels [25(OH)D] and the frequency as well as the evolution of knee, hip or hand OA. In 3 cross-sectional studies, however, there was found a correlation between the low levels of 25(OH)D and the stenosis of knee joint space (OR=1.52, 95% CI:1.15-2.01). The meta-analysis of the above-mentioned three studies did not show a significant correlation between the low levels of

25(OH)D and the evolution of knee OA (OR=1.37, 95% CI:0.97-1.92). However, when only patients with progressive knee OA development were assessed, an increased risk was found in patients with low levels of 25(OH)D (OR=2.40, 95% CI:1.22-4.72) [30]. In a study of 149 patients (133 women, mean age 63.6 years) with knee OA, the vitamin D deficiency rate [25(OH)D<10 ng/mL] was estimated at 90% [31]. Chaganti RK et al. conducted a study in 1104 elderly men who participated in the "Osteoporotic Fractures in Men Study", measuring 25(OH)D levels at the beginning of the study and performing a radiographic hip examination 4.6 years later. It was found that higher levels of 25(OH)D at the beginning of the study were associated with a lower risk for 25[OH]D decrease, while men with vitamin D deficiency compared to men with normal vitamin D levels had a significantly higher risk (OR=2.19, 95% CI: 1.21-3.97) of developing hip OA [32]. Zhang FF et al. in 418 patients with clinical and radiographic knee OA found a correlation between low 25(OH)D levels and the risk of developing OA radiographically as assessed by evaluating the joint space stenosis (<15 μg/L compared to ≥15μg/L) [33,34]. On the other hand, Lane NE et al. radiographically attended the hips of 237 individuals (with an interval of 8 years) and found no correlation between levels of 25(OH)D and serum 1.25(OH)2D and OA risk progression (development of osteophytes and/or reduction of the joint space) [35]. In addition, Bergink AP et al., in 1248 elderly people (728 women and 520 men) who participated in the prospective study (Rotterdam Study) assessed the development and progression of OA knee radiographically (average follow-up time 6.5 years), found no correlation between 25(OH)D levels (at the beginning of the study) and the risk of subsequent knee OA [36]. In a cross-sectional study of 99 patients (90 women and 9 men, aged 36-80 years) with clinical and radiographic knee OA, no correlation of low 25(OH)D levels with clinical and radiographic OA severity was found [37].

EFFECT OF VITAMIN D ON CLINICAL MANIFESTATIONS OF OA

Some studies have found a correlation between low serum vitamin D levels in patients with OA and joint pain as well as limited physical activity, and quality of life, while some other studies did not. In Zheng S et al.'s study, in 340 patients with OA knees, a correlation of low levels of 25(OH)D was found with severe limitation of the patient's functionality [28]. Levinger P et al. in a study of 24 patients (68.6 ± 6.2 years) with clinical symptoms of knee OA, found a correlation between low levels of 25(OH)D (deficiency ≤50 nmol/L) and knee pain and restriction of patients' functionality [38]. In another study of 100 patients with knee OA, it was found that the vitamin D deficiency group had more severe knee pain, more severe physical limitations, a more intense feeling of fatigue, and a worse quality of life [39]. On the other hand, Lee A et al. evaluated 3824 people aged >65 years (Korean National Health and Nutrition Examination Survey) and found that the levels of 25(OH) D were not related to knee pain [40]. Also in another study of 149 patients (133 women, mean age 63.6 years) with knee OA, no correlation was found between low levels of 25(OH)D and knee pain [31].

CORRELATION OF VITAMIN D LEVELS WITH MUSCLE STRENGTH IN PATIENTS WITH OA

Of particular clinical importance is the association between vitamin D levels and muscle strength (primarily of the lower extremities muscles such as quadriceps that support the weight-bearing joints) of patients with OA (primarily knee OA). A study found that normal levels of vitamin K and vitamin D were associated with better lower extremity function [41]. Javadian Y et al. found a positive correlation between 25(OH)D levels and quadriceps muscle strength in 92 patients with knee OA knee (≥40 years old) (r=0.304, r=9.24%, p=0.005). For every increase of 25(OH)D levels by 1 ng/mL, the strength of the quadriceps increased by 14.2%±3.5% (p=0.014) [42]. In a 24 patients study (68.6 ± 6.2 years) with OA knee clinical signs, a correlation between low 25(OH)D levels (deficiency in ≤50 nmol/L) and the reduction of quadriceps muscle strength was found [39].

However, the effect of other factors, such as body mass index, should be also assessed. In a cross-sectional study of 319 patients with knee OA, a significant correlation between serum levels 25(OH)D and strength of the upper tibial muscles were found, which, however, ceased to be observed when the effect of the body mass index was estimated [43].

CORRELATION BETWEEN VITAMIN D LEVELS AND THE POSSIBILITY OF AN UNDERGOING ARTHROPLASTY IN PATIENTS WITH OA

Numerous researchers have investigated whether vitamin D levels in patients with OA are associated with the possibility of undergoing arthroplasty (mainly hip and/or knee arthroplasty) as well as their postoperative follow-up. A high percentage of low vitamin D levels was found as well as less satisfactory follow-up in patients with low levels. In a recent literature review (12 studies, 2593 patients) the percentage of patients with OA who underwent hip or knee arthroplasty with hypovitaminosis D was estimated at 47% (34.02% -59.9%) [44]. In another study, in 164 patients with hip or knee OA who were to undergo arthroplasty, vitamin D deficiency was found in 81.7%, especially in men [45]. Elevated vitamin D levels are likely to reduce the risk of OA patients undergoing total hip arthroplasty. Hussain SM et al. studied 9135 patients ≥40 years old, who participated in the Australian Diabetes, Obesity and Lifestyle Study, in which the levels of 25(OH)D during 1999-

2000, as well as the percentage of hip arthroplasty in 2002-2011, was estimated (Australian Orthopedic Association National Joint Replacement Registry). 201 patients with OA (90 men and 111 women) underwent hip arthroplasty. In men for any one-standard-deviation increase in levels of 25(OH)D, the probability of undergoing the operation was reduced by 25% (HR=1.25 and 95% CI 1.02-1.56) but not found in women (HR=1.10 and 95% CI 0.87-1.39) [46].

Regarding the effect of low vitamin D levels in patients with OA who have undergone arthroplasty, it appears that they are associated with less satisfactory postoperative results. In Zhang H et al.'s review, it was found that patients with OA who underwent hip or knee arthroplasty, and hypovitaminosis D adversely affected the postoperative results of these patients (Harris Hip Score score was higher in these patients compared to patients with normal vitamin D levels) [44]. In a study conducted in 2010, 62 patients who underwent total hip arthroplasty were compared with 62 patients of the same sex and similar age from the control group, it was found that the patients with vitamin D deficiency had less satisfactory postoperative follow-up results (p=0,038) as well as they had the lowest preoperative Harris Hip Scores (Mann-Whitney test, p=0.018) [47]. Maniar RN et al. also studied 120 patients with OA who underwent total knee arthroplasty [53.3% had preoperative levels 25(OH)D<30 ng/mL]and they assessed their functional ability before and 3 months after surgery. Before surgery, in patients with vitamin D deficiency, their functional ability was limited [Western Ontario and McMaster Osteoarthritis Index (WOMAC), p=0.040]. After surgery, in patients who received vitamin D supplementation, their functional ability was restored, which was similar to the functional ability of patients with normal vitamin D levels [48]. On the other hand, in the study of Visser E et al. in 87 patients with OA who underwent total hip arthroplasty, no correlation was found between levels of vitamin D and restoration of hip function. However, an increase in levels of 25(OH)D was observed six months after surgery, which was associated with an improved hip function (Pearson's r =-0.471, p=0.018) [49].

Regarding the dosage of postoperative vitamin D administration in patients with OA who underwent arthroplasty, there are interesting results from a randomized, double-blind 24-month study of Bischoff-Ferrari et al. in which participated 273 patients underwent knee arthroplasty. 137 patients received 2000 IU of vitamin D while 136 patients received 800 IU per os daily. Even though the administration of 2000 IU was accompanied by a significant increase in 25(OH)D levels (45.6 ng/mL vs 37.1 ng/mL of the 800 IU dose after 24 months, p <0.0001). No difference regarding the restoration of operated knee function, nor on the radiographic progression of the other knee OA, between the group of patients who were administered 2000 IU and 800 IU respectively (30,5% vs 31,3%, p=0.88) [50].

THE ROLE OF VITAMIN D SUPPLEMENTATION IN PATIENTS WITH OA

Animal studies have shown that vitamin D has a protective effect on the articular cartilage architecture [51,52]. In an animal study, micro swings that were on a diet rich in cholesterol, it was found that vitamin D had a protective effect on the architecture of articular cartilage (reduction of inflammation and fat infiltration) [51]. In Li S et al.'s animal (ovariectomized rats) study, was also found that vitamin D deficiency was associated with deterioration of the knee articular cartilage, while the administration of 1,25(OH)2D3 with a protective effect on articular cartilage [52].

Vitamin D supplementation in patients with knee OA has been associated with a reduction in synovial membrane thickness and joint effusion associated with the OA development, as well as an improvement in knee articular cartilage architecture [53,54]. In a study of 413 women with symptomatic OA knee and low 25(OH)D, 209 women were supplemented with vitamin D (50,000 IU per os monthly) while 204 women were administered placebo for 24 months. This study investigates the effect of this administration on the articular membrane thickness and joint effusion using MRI. The rate of increase of the above-mentioned variables was lower in the group supplemented with vitamin D compared to the placebo group (risk ratio (RR)=0.87, 95% CI: 0.77-0.97) [53]. Veronese N et al. in 783 patients with knee OA (59.8% women, mean age 62.3 years), vitamin D supplementation was evaluated for its effect on the volume and thickness of the medial and lateral femoral condyle cartilage with MRI. Using linear regression analysis in which the effect of 10 potential confusing factors was assessed, it was found that vitamin D supplementation led to an increase in the volume and thickness of the medial and lateral femoral condyle cartilage, suggesting an improvement in its architecture [54].

Several studies have investigated the effect of vitamin D supplementation on joint pain, quality of life, physical function, joint stiffness, muscle strength (such as quadriceps femoris), joint space range, articular cartilage volume, and deficits as well as bone marrow lesions, etc, with conflicting results [55]. Moreover, in a systematic review and meta-analysis conducted in 2017, it was found to be small as a moderate result of vitamin D supplementation in knee pain [standardized mean difference (SMD)=-0.32, 95% CI: -0.63 to -0.02]. However, no effect was found on tibial articular cartilage volume/thickness (SMD=0.12, 95% CI: -0.05 to 0.29) or joint space range (SMD=0.07, 95% CI: -0,08 to 0.23). In other words, vitamin D supplementation had a rather favorable effect on knee pain but not on OA severity [56].

In all randomized controlled trials, 25(OH)D levels were found to increase in patients supplemented with vitamin D compared to patients that took the placebo. However, no reduction in pain (except for one study) or knee stiffness (evaluation with WOMAC scale) was found. On the other hand, in 2 of 3 studies that assessed knee pain using a visual analog scale (VAS), vitamin D supplementation led to an improvement in knee pain [57]. In Heidari B et al.'s study, 67 patients (aged ≥30 years with knee OA) received a supplement of 50,000 IU of cholecalciferol per week orally for at least two months. It was found that the cholecalciferol supplementation led to an increase in the normal level of 25(OH)D ($p=0.007$) as well as to a significant increase in quadriceps strength ($p=0.002$) and a significant decrease in knee pain ($p=0.001$) to all patients (except for one patient) [58].

In a multicenter randomized double-blind study, 340 patients with symptomatic knee OA were distinguished into one group of patients who received vitamin D (50,000 IU per month orally) and another group that received a placebo two years ago. The purpose of the above-mentioned study was the evaluation of this administration's effect on tibial articular cartilage volume, the presence of defects in tibial articular cartilage, bone marrow lesions, and knee pain. There was a significant increase in 25(OH)D levels in the supplemented group compared to the placebo group (40.6 nmol/L vs 6.7 nmol/L, $p<0.001$). However, no effect was found on tibial joint cartilage volume, the presence of tibial joint cartilage deficits, or bone marrow lesions as assessed by MRI [59].

Additionally, in a study of 175 patients with primary knee OA and low levels of 25(OH)D (<30 ng/mL), they were supplemented with 40,000 IU of vitamin D (ergocalciferol) per os once a week for six months. It was found significant increase in 25(OH)D levels ($p<0.001$), improved quality of life ($p=0.005$) and patients' functionality ($p<0.05$), as well as reduced knee pain ($p=0.002$) [60]. On the other hand, in a three-year double-blind, randomized study of 474 patients aged>50 years with radiological signs of knee osteoarthritis, it was found that the group of patients supplemented with vitamin D led to an increase at 25(OH)D levels compared to the placebo group, without affecting the narrowing of the joint space, pain, function, or stiffness of the knee joint [61].

The administration of high-dose vitamin D supplements has a rather beneficial effect on reducing knee pain. A meta-analysis of 4 randomized group studies with 1,136 patients, evaluated whether and to what extent the administration of a vitamin D supplement affects pain, function, stiffness, and tibial joint cartilage volume of patients with knee OA. It was found that this administration was associated with pain reduction and improved function but did not improve knee stiffness or tibial joint cartilage volume. Particularly favorable was the effect on pain and knee function in patients receiving a dose of natural vitamin D higher than 2000 IU [62].

It was also studied whether vitamin D supplementation and maintaining adequate levels affected inflammatory markers and metabolic biomarkers associated with OA pathogenesis. Zheng S et al. studied 413 patients with symptomatic knee OA and vitamin D deficiency, who were randomly assigned to one group receiving 1.25 mg of vitamin D3 and to another group receiving a placebo, once a month for 24 months. The researchers concluded that vitamin D supplementation as well as maintaining adequate levels did not affect inflammatory markers or metabolic biomarkers [63].

CONCLUSIONS

In conclusion, low levels of vitamin D in patients with OA rather adversely affect the structure and function of articular cartilage. They are associated with joint pain, limited physical activity, quality of life, etc, as well as decreased muscle strength, primarily of the lower extremities with adverse OA progression. A high percentage of low vitamin D levels was found in patients with OA and joint arthroplasty as well as less satisfactory postoperative progress in patients with these low levels. The administration of vitamin D supplementation in patients with knee OA has been associated with improved articular cartilage architecture and reduced joint pain in combination with improved function and quality of life.

REVIEW

Biotribology of the Total Hip Replacement – Review of the Current Bearing Surfaces

Abstract: *Total hip replacement surgery (THR) is one of the most common surgeries performed in modern orthopedics, and in most cases offers a significant improvement in the quality of the patient's life. However, after some time, wear and osteolysis do appear, which leads to the need for revision surgery. With the indication being widened to a more young and active population, the need for extending the lifespan of the prosthesis is mandatory. Although several bearing surfaces have been studied over the years, and a lot of couplings are in use, the choice of the right combination of materials is still controversial. Biotribology tries to answer some of the current questions regarding the best bearing surface to use, being the branch of science and technology that studies friction, wear, and lubrication of different materials in the human body. In the present day, a large number of materials are in use for total hip replacement, but choosing the right combination of materials is still controversial, and is being done on one hand by the surgeon's experience and on the other hand by the age and activity of the patient. The objective of this review is to try to present the main advantages and disadvantages of different materials and try to answer the most difficult question of them all: What is the right material to use for THR-bearing surfaces?*

Keywords: *total hip replacement, tribology, biotribology, arthroplasty*

INTRODUCTION

More the 350,000 total hip replacements are done each year in the United States [1], with a constantly increasing rate. The survival rate of these implants is, according to the British National Joint Registry, 93.2% at 13 years, and 80% up to 20 years [2]. Although these rates seem to be pretty good, about 13% of these hip replacements are revision arthroplasties [3]. This high rate can be attributed to the younger and more active patients who were treated with this procedure.

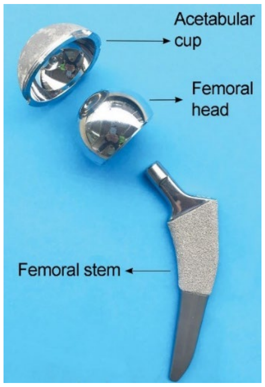
The most important aspect is still worn, which limits the lifespan of this prosthesis to 10 – 15 years. With a lot of materials and couplings to choose from, such as hard-on-soft bearings like metal-on-polyethylene (MoP) and ceramic-on-polyethylene (CoP), and hard-on-hard bearings such as ceramic-on-ceramic (CoC), metal-on-metal (MoM) and ceramic-on-metal (CoM), it can be confusing for both the patient and the physician, all of these materials showing specific wear mechanisms and characteristics that will be discussed in the present paper. Wear patterns like burnishing, abrasion, pitting, and scratches were observed for ultra-high molecular weight polyethylene (UHMWPE) and cross-link polyethylene (XLPE) [4], stripe wear was observed for ceramic components [5], changes in surface characteristics like roughening and roundness for metal-on-polyethylene couplings [6], gouging, scratching and polishing for metal-on-metal couplings [7].

Metal-on-metal couplings

With the first implantation in 1938 by Wiles, the MoM coupling was the first bearing used for THR. In conventional metal-on-metal hip replacements, the prosthesis is made up of a large diameter metallic femoral head on a standard femoral stem that articulates with a metal acetabular cup or liner, CoCrMo alloy was used widely for these bearings (Figure 1).

The advantages of this type of coupling are that they could be engineered to be extremely smooth and hard, properties that can reduce the wear rate, and the wear rate of MoM is estimated to be 60 times less than conventional MoP implants [8]. Other advantages include increased resistance to dislocation associated with large-diameter heads and reduced osteolysis due to the absence of polyethylene particles [8].

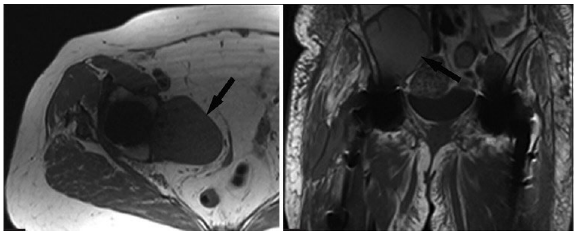
Figure 1: Metal on-metal coupling [10]



On the other hand, MoM materials come with a series of disadvantages. The metal alloys used in orthopedic implants degrade due to wear and, unlike polyethylene, also corrosion. This can lead to soft tissue inflammatory reactions to metal debris, known as adverse reactions to metal debris. The rate of wear depends largely on the contact force between the two surfaces and the sliding distance, and thus increases with physical activity, weight gain, larger implants, and the roughness of the implant surface [9].

The **inflammatory pseudotumors** (Figure 2) represent the existence of an aseptic mass in the periprosthetic tissue that can be solid or cystic and associated with local inflammation [11]. It is believed that it develops as a result of an adverse reaction to the metal ions released from the wear of metal articular bearing surfaces [12]. Implanting the acetabular cup at abnormal inclination angles increases the edge loading which leads to increased prosthetic wear [13]. The incidence of pseudotumors is up to 32% in some studies [14]. In a study conducted in 2009 on 1224 patients, it was shown that female patients and those under 40 years of age had an increased risk of revision due to pseudotumors [15].

Figure 2: The inflammatory pseudotumors [16]

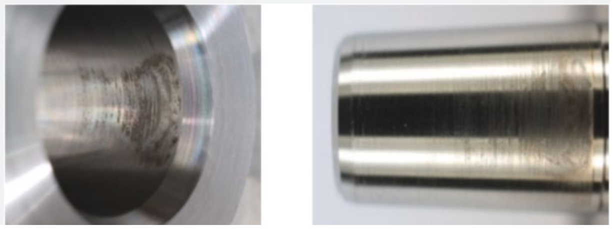


Aseptic lymphocytic vasculitis-associated lesion (ALVAL), consists of cellular changes that occur as a response to cobalt and chromium ions. The mechanism is believed to be a T lymphocyte-mediated type 4 hypersensitivity reaction, with tissue damage occurring as a result of cytotoxic T cells and activated monocytes/macrophages].

Metallosis, represents aseptic fibrosis, local necrosis, or aseptic loosening of a device because of metallic corrosion and release of wear debris [18].

Trunnionosis (Figure 3), the metal wear at the head-neck junction of a total hip implant is believed to be an important contributor to the release of metal particles [19]. It is present in the modular design prosthesis, both in MoM and MoP, because in both cases the head-neck junction is made up of metal-on-metal surfaces. This is the main reason why trunnions cannot be blamed to be the only cause of the increased rate of adverse reactions in MoM hip replacements.

Figure 3: Trunnionosis [20]



Revision rates for MoM at 10 years for cemented and uncemented hip replacements are 19.68% and 21.92% by comparison with MoP, which was 3.13% and 3.98% [21]. There seems to be a direct connection between the size of the femoral head that was used and wear, in THR that used a head size above 40mm the revision rate at 10 years was 25.5%, by comparison to those that used a femoral head diameter below 28mm with a revision rate at 10 years of just 5.7%.

Serum and urine ion levels produced by MoM bearings are similar to the ones produced by the modular junctions of femoral components. The toxicologic importance of these trace metal elevations has not been established. Because the wear of a THR with an MoM bearing cannot be evaluated radiographically, metal ion concentrations in serum and urine can be indicators of wear [22].

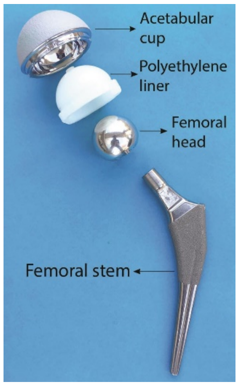
Considering the renal excretion of Co-Cr ions, a potential for increased risk of bladder and other cancers in patients with metal-on-metal couplings was formulated. Two large studies were conducted in England and Wales and Finland that examined nearly 330.000 patients [23,24], but no connection between MoM bearings and the high risk of developing a type of cancer was discovered. The follow-up protocol within those studies was seven and four years. So, we think that studies with a longer follow-up period are needed to completely declare that MoM implants do not increase the risk of cancer development.

Due to all of these considerations, in the present day, the MoM THR is almost entirely abandoned by surgeons and withdrawn from the market by manufacturers [25].

Polyethylene

Conventional and cross-linked polyethylene liners are the most common choice in THR. First used by Charnley in 1962 [26], this polymer is a high molecular weight polyethylene with extremely long chains. Until the mid-2000s, the MoP bearings (Figure 4), with head diameters between 22 mm and 32 mm we're considered the standard. The linear wear for PE is between 100 to 300 µm/year [27], which corresponds to volumetric wear of 20 – 150 mm^3/year for 28 mm heads [28]. It was shown that a correlation exists between volumetric wear and the risk for osteolysis, every increase in the amount of volumetric wear of 40 mm^3/year triples the long-term risk of osteolysis [29].

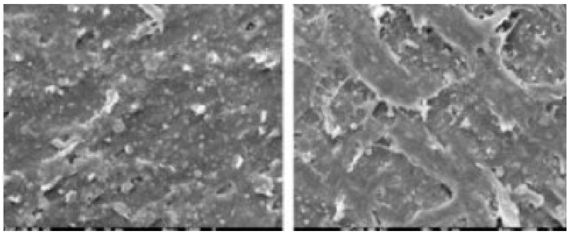
Figure 4: Metal on polyethylene coupling [10]



When using polyethylene liners, not only the material is important, but also the sterilization technique, because this too can influence the mechanical properties and biological effects. The most common sterilization method used was gamma irradiation. Some studies [30] show that this sterilization method increases cross-linking between polyethylene molecules offering a more wear-resistant material. But, when this is done in the presence of oxygen, free radicals are released that can oxidate and make the liner more brittle with reduced resistance and increased wear. So, thermal sterilization with gas plasma was shown to improve wear and oxidation resistance [30, 31], and oxygen-free gamma irradiation showed less head penetration and less osteolysis [32].

Because of the wear debris of the conventional polyethylene, cross-linked polyethylene was developed (Figure 5). It is obtained by irradiation of conventional polyethylene with at least 50 kGy of gamma beam radiation, which induces the cross-linking between PE molecules, which increases wear resistance [33]. The rate of revision at 16 years for XLPE was 6.2% vs. conventional PE which was 11.7% [34]. The process of cross-linking can however decrease the mechanical properties so that the liner can become at risk for fatigue fracture because the irradiation process releases free oxygen radicals [35]. In addition, steep positioning of the acetabular cup leads to stress concentration or impingement and it is considered also a risk factor [36]. This problem was solved by introducing vitamin E into the liners, which is an antioxidant, and the mechanical properties are saved. Also, the liners can be now thinner and the femoral head bigger, which can improve joint stability.

Figure 5: Cross-link polyethylene–electron microscopy [37]



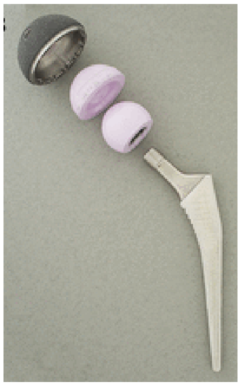
When evaluating the long-term resistance of PE, conventional or cross-linked, we must take into consideration also the femoral head material and diameter. We know that the larger the femoral head diameter the bigger the wear, especially when coupled with conventional PE [38]. It seems that this does not apply to XLPE, where the wear rate is not higher for bigger head diameters [38].

In the matter of ceramic vs. metallic femoral heads, in early studies, the average wear rates with the metal femoral head (stainless steel and cobalt chrome) invariably were higher than with ceramic femoral heads [39-41]. In a more recent study based on a systematic analysis of registry data, an overall equal long-term performance was found between metal and ceramic heads, although a lower revision rate was discovered with CoXLPE than MoXLPE [38]. The advantages of ceramic heads are higher hardness with less risk of damage during implantation, the surface finishing with only negative peaks due to grains detachment rather than deformation, and higher wettability which means better lubrication of ceramic, less friction and scratching and less linear wear [27]. Last, but not least, alumina is biologically inert and has the best biocompatibility.

Ceramic on ceramic

Alumina and zirconia ceramic is used in THR surgery (Figure 6). Alumina has a very low friction coefficient, is biocompatible, and its material properties are not affected by aging it was also shown that it reduces volumetric wear [33]. With the risk of fracture being the most severe concern, alumina (82%) was mixed with zirconia (17%), chromium oxide (0.5%), and strontium crystals, and a higher resistance to crack and enhanced hardness were obtained. With this breakthrough, the fracture rates of the femoral head were reduced from 0.021% to only 0.003% [42]. However, the risk of ceramic head fracture is still lower than the risk of ceramic liner fracture (0.003% vs. 0.03%) [43]. The survival rate at 10 years of these implants in excellent, varying from 98% to 99.3% [44], 92.8% at 15 years [34], and 84.4% at 21 years [45].

Figure 6: Ceramic on ceramic coupling [46]



The advantages of CoC bearings are a very low friction coefficient and very low wear rates, due to high wettability and hardness. If however, the ceramic implant does suffer wear, the particles released are biologically inert and produce a less biological reaction. Another great advantage is that the wear is not dependent on the diameter of the femoral head, a large femoral head will provide a more stable artificial joint with a low risk of dislocation. A recent study showed that 36mm ceramic femoral heads had a lower revision rate than smaller 28mm ceramic femoral heads [47]

Like any other bearing surface, the CoC coupling also has a series of drawbacks. Although the risk of fracture was lowered as presented, the risk remains and is a catastrophic complication that requires revision surgery. Factors that can increase the liner fracture risk are misalignment during insertion of the liner, metal back damage or acetabular component malposition that can lead to edge loading, and the most important factor, excessive anteversion.

Another disadvantage is the noise that this coupling can produce. Clicking, grinding, clunking, and squeaking has been described. The incidence varies from 0.7% to 20.9% [48], this adverse event can even be a cause of revision, with a rate of 0.2% [49]. Risk factors for squeaking are age, obesity, activity level, soft tissue balancing, and positioning of the acetabular cup.

It is recommended that in cases with severe posttraumatic acetabular deformities or severe developmental dysplasia of the hip, the CoC should be avoided, because of the difficulty of correct positioning of the acetabular component.

Another drawback of the CoC bearing is the cost. It is the most expensive choice of coupling, but also the most advanced and resistant to wear when used correctly.

DISCUSSION

After the literature data has been analyzed, we concluded that the preferred choice when it comes to total hip arthroplasty bearings is a hard-on-soft coupling like the metal (cobalt-chrome) on polyethylene or ceramic on polyethylene. MoPs are still the most widely used coupling covering about 60% of all interventions, but the use of CoP is increasing. But which of the two is better?

If we consider the studies of wear screening using water-based lubrication and linear tracking, there is a 20-to-80-fold advantage for ceramic-on-polyethylene when compared with metal-on-polyethylene [50]; however newer wear studies with high protein concentrations have shown similar wear with alumina or with met-al-on-polyethylene [51]. Because of the biological advantages of alumina which is biologically inert and with the amount of literature that supports the superiority of the ceramic femoral head, we too recommend the use of ceramic-on-polyethylene bearings over the metal-on-polyethylene ones.

Considering the type of polyethylene that should be used, we feel that is enough literature that proves that conventional polyethylene has a much higher wear rate than cross-link polyethylene. More and more manufacturers are offering just the cross-link version now, the only advantage of the standard polyethylene is the lower cost of production. However, we feel that because of the high wear rate that requires early revision, there is practically no cost advantage, and therefore we cannot recommend using conventional polyethylene anymore.

How about hard-on-hard surface bearings? We know that the manufacturers do not provide the MoM bearing anymore, due to the pseudotumors caused by toxic metallic ions, so the only valid option for this kind of bearing is the CoC.

Although the wear is insignificant with this coupling and is not associated with femoral head diameter, there is still concern about motion sounds like squeaking, which has a revision rate that varies between 1 and 21%. Another drawback is the risk of liner fracture; although is a quite low risk, it has a catastrophic impact and requires urgent revision surgery. So, there is still room for improvement.

CONCLUSIONS

Deciding what coupling to choose is mostly dependent on the surgeon's preference and experience. Considering the literature mentioned in the present paper we recommend the use of CoC bearing if the cost is not an issue, in young and high-activity demanding patients, with a large diameter femoral head, up to 36 mm, as wear is not related to large head diameter femoral heads and can improve joint stability. Care must be taken in cases where the correct positioning of the acetabular component may be an issue, as the malposition of the acetabular cup can lead to squeaking and increase the risk of fracture of the ceramic liner.

CoXLPE is a good option for CoC, with a lower cost and offers comparable results. It can be successfully used in active patients over 60 years of age, care must be taken in choosing the right femoral head, larger diameter head being associated with a higher wear risk. We cannot find any reason for using conventional PE, as it proved to be less reliable and more susceptible to wear, with a higher risk of releasing debris.

The choice of MoXLPE remains a viable option in a situation in which cost is an issue. Other than cost-related issues, the ceramic bearings are a more reliable option over the metallic on PE.

Even if the best bearing surface is available, we should not forget that coupling is not everything, and careful patient selection is still mandatory. More than that other factors influence the overall behavior of the THR, like age, level of activity, anatomic deformities of the acetabulum, positioning of the components, bone quality, soft tissue balancing, and patient compliance. So, to have a successful THR all of these factors must be carefully quantified, and the surgeon must use the correct surgical technique.

Abstract: *A successful nose reconstruction is represented by a normal look and nasal breathing preservation. The choice of method is based on the site, size, depth of the defect, donor availability, and surgeon experience. There are multiple methods of restoring nasal cover, from primary repair to healing by secondary intention, from primary suture, skin graft to locoregional flaps, but all of them should be integrated into a personalized approach, keeping the nasal functions, a good aesthetic outcome and without any tumor infiltration. This paper consisting of a retrospective study of 9 patients diagnosticated with squamous cell carcinoma revealed the importance of skin properties and skin changes during aging. Despite all aesthetic principles, skin is the most important resource in facial reconstruction.*

Keywords: *nose reconstruction, aesthetic, squamous cell carcinoma*

INTRODUCTION

Cutaneous squamous cell carcinoma is one of the most common skin cancer with an increasing incidence [1]. Most frequently on sun-exposed sites, like the face, it could be a challenge for a surgeon [2]. One, because of its aggressiveness and the possible requirement of large excisions, and second, because of the psychological impact on the patient. The nose is one of the most visible anatomical sites so, an aesthetic result is even more required. The nasal restoration should be based on keeping the contouring, color, and texture, minimalizing the scars, and preserving the breathing function [3].

MATERIALS AND METHODS

A retrospective study performed in the Plastic Surgery Department of Emergency University Hospital, Bucharest, Romania evaluated 9 patients diagnosticated with cutaneous squamous cell carcinoma at the nose level through the histological exam, two of them with local relapse. The age average was 63 years old, with a minim of 44 years old and a maxim of 90 years old. It was identified as a male prevalence.

In all cases, the tumor resection was performed with free macroscopically oncological edges. Depending on the tumor size, site, and patient age, multiple reconstruction techniques were required. In 4 cases primary suture was practiced, in 3 cases local flaps were required, and in 2 cases skin grafts.

All the patients signed the Informed Consent before surgery and the study was approved by Ethics Committee.

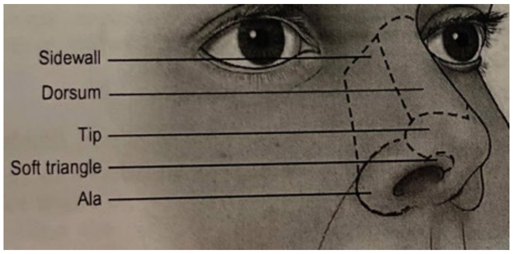
DISCUSSION

There are nine aesthetic subunits of the nose, dorsum, paired sidewalls, nasal tip, paired alae, columella, and paired soft tissue facets (Figure 1). The concept of aesthetic units in nasal reconstruction was first described by Millard to improve surgical results. Then, Burget and Menick introduced the principles of nose aesthetic subunits which improved the aesthetic results in nose reconstruction [4].

The skin quality is different in every aesthetic subunit, being thicker at the nasal tip, nasal alae, and cranial dorsum, and upper nasal sidewall and mid-lower dorsum being the thinnest. In all facial reconstructions, the skin patient is an important factor. During aging, the skin properties are changing and the skin becomes looser.

Nose reconstruction is a complex process in which the first step should be defect identification. A classification of nasal defects is based on size. There are small defects, with a diameter of less than 1.5 cm, and large defects, with a diameter over 1.5 cm, which require a skin graft or a local flap [5].

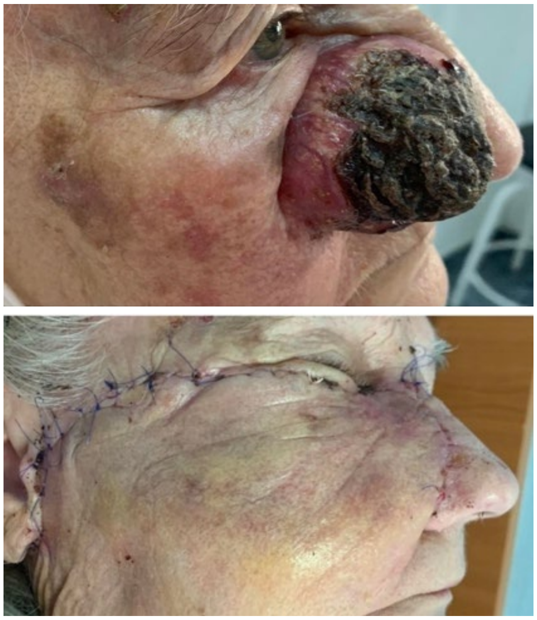
Figure 1: Nose aesthetic subunits



Depending on the depth of injury, there are superficial defects where the skin is missing and also, a small underlying subcutaneous fat and nasalis muscle could be missing. Deep defects are represented by the absence of an underlying supportive framework or lining. The cartilage could be affected, so a composite skin graft could be required, cartilage grafts, or vascularized regional flap for cover [6].

A more complex reconstruction is required by composite defects which are represented by nose defects extended to the cheek or upper lip (Figure 2). The challenge consists of the fact that they are different aesthetic units. The reconstruction of composite defects should be based on keeping the quality, outline, contour, projection, and function of each one, not only to “fill the hole”.

Figure 2: Nasogenian tumor that left a composite defect including sidewall, ala, dorsum, and cheek, which was covered by a local cheek flap



Choosing the reconstruction method should be based on the shape, size, location, and depth of the defect and the aesthetic unit involved [7]. The bilobed flap is one of the most common local flaps used in nose reconstruction, especially for tip and ala defects, when the diameter of the defect doesn`t count more than 1.5cm [8]. The Bipedicle mucosal flap could be useful in small alar reconstruction to keep the lining of the nose [9].

Another common flap in nose reconstruction is the septal hinge flap which is used for tip, ala, and sidewall defects [10]. The technique is based on the anterior septal artery. When the nasal tip and columella are missing, and also a part of the septum, bilateral septal flaps could restore the lining of the ala and nasal vestibule [11,12,13].

In cases of full-thickness defects, especially for lateral defects, the inferior turbinate flap could be a good option, alone or together with other techniques [14].

Forehad flap is useful for any significant nasal defect over 2.5 cm. It can be also used when the septal hinge flap and inferior turbinate flap failed. The technique is based on the supratrochlear vessels that pierce the orbital bone at about 2 cm lateral to the midline [15].

Melolabial flap in an interpolated flap is used for defects less than 4 cm, especially for cutaneous nasal ala defects with or without modest extension into the tip and sidewall [16].

The aesthetic outcomes between local flaps and skin grafts are depending on patients' selection. Sapathavee, Munaretto, and Toriumi proved that a skin graft provides an aesthetic result in patients with Fitzpatrick types 1 and 2 skin, also with thin and less sebaceous skin. The preauricular skin offers a good match in nose reconstructions. Some authors are using “skin fat grafts” to fill small deep defects of the nose [17].

Keeping the structure of the nose is an important part of the reconstruction. Cartilage grafts are useful tools in maintaining nose support. They prevent also overlaying soft tissue contraction, minimize pincushion deformity and reduce nasal obstruction. The donor sites could be costal cartilage or calvarial bone for restoring the contour and support of total or subtotal nasal defects, and conchal cartilage for alar reconstruction due to its curvature shape.

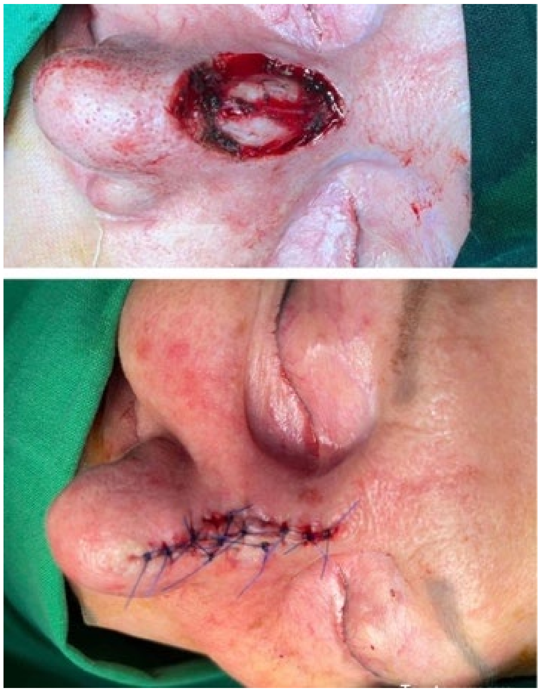
To keep the internal lining, a composite graft from the conchal site could be used. Also, a composite graft from the helix root could be used in nasal ala restoration [18].

In our case, we used skin grafts in 2 cases of female patients, about 63 and 69 years old. The tumors had the same localization, at the dorsum level, and has a diameter over 3 cm, without bone invasion.

In 2 cases of the cutaneous tumor with approximately 1.5 diameters, at the sidewall and ala levels, local flaps were performed. The nasolabial transposition flap was the reconstruction method for ala defect, while for sidewall defect a dorsal nasal flap was performed. Rieger described the dorsal nasal flap as a laterally-based rotation flap with a wide pedicle. The technique consists in designing a "V" in an upside-down fashion over the glabella and then a curvilinear line on the nasal–cheek junction till it reaches the defect site. Marchac and Toth updated the Rieger version by narrowing the pedicle in an axial flap based on the vessel arising from the inner canthus. The advantages consist in increasing mobility, decreasing wound closure tension, and a more precise adjustment [19].

One case of a cutaneous tumor involving multiple nasal subunits, with a diameter over 4 cm, without bone invasion, required multiple techniques of reconstruction, frontal flap for dorsum defect, and primary suture for secondary defects.

Figure 3: Intraoperatively picture with dorsum defect size after squamous carcinoma resection for which the skin allowed a primary suture.

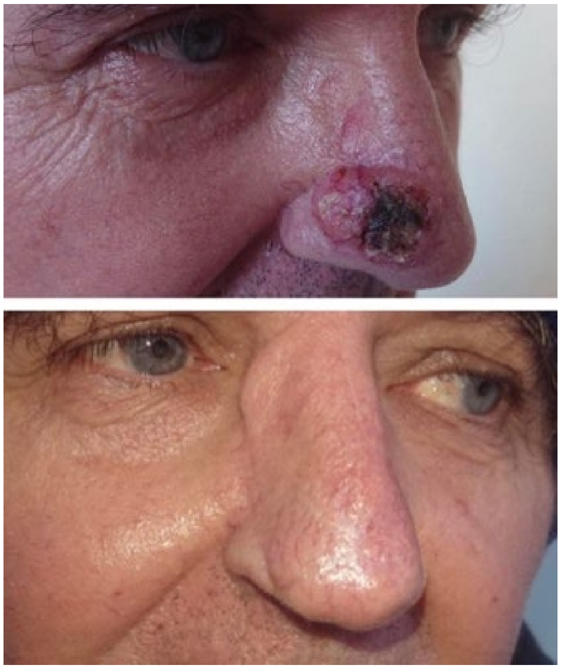


In 4 cases, the primary suture was enough for closing the defect. Three of them had a diameter less than 1.5 cm, one at ala level and 2 at dorsum level, with ages between 59 and 80 years old. There was another case of 77 years old female, with a diameter tumor of approximately 2.5 cm at the dorsum level, for which the primary suture was enough (Figure 3). Usually, a defect of 2.5 cm isn`t suitable for primary suture and a local flap is mandatory. For defects of 1.5 cm – 2.5 cm, a dorsal nasal flap, a bilobed flap, or a glabellar flap could be used [20].

So, depending on the aesthetic unit involved and defect size, nasal reconstruction methods differ. Choosing the reconstruction method should be based on restoring the aesthetic unit, not on filling the defects. Keeping a natural look, the borderline, the skin quality, and preserving the breathing function are variables that we should take into account in nose reconstruction, but free tumor edge is the most important medical approach. Dorsum and sidewalls have common skin characteristics, so the reconstruction methods are similar. Defects less than 1.5 cm could be closed primarily, with a glabellar flap or a transposition one. Defects with a diameter of 1.5-2.5 cm require a local flap, a glabellar flap, a bilobed flap, or a dorsal nasal flap. The last one can be also used for defects more than 2.5 cm [21].

In case of nasal tip defects, a bilobed flap can be used for defects less than 1.5 cm, a dorsal nasal flap under 2.5 cm, and forehead flaps for defects of or bigger than 2.5 cm (Figure 4).

Figure 4: Skin tumor involving ala unit which required a forehead flap



In case of nasal ala defects, a full-thickness skin graft and a cartilage graft to keep the shape and to avoid breathing obturation is a good choice for superficial defects, while in case of deeper defects, a more complex reconstruction like nasolabial flap or interpolated melolabial flap is required [22].

Despite all the reconstruction science of skin defects, skin properties are changing during aging which requires a personalized surgical approach.

Even if the resection was performed with free macroscopical tumor edges, the histological exam revealed a deep tumor infiltration in 5 cases, which showed the limitation of anatomical site between safe tumor resection with free tumor edges and aesthetic result.

CONCLUSIONS

Since the nose is the most visible part of the body, its reconstruction has an important role in the life quality of patients. Behind the science, plastic surgery is also about art and understanding that skin suffers changes during aging which affects its properties, its structure and requires a personalized approach. Every nose reconstruction should be based on keeping a three-dimensional contour, keeping the quality of the skin, the border outline, and breathing function. All the techniques should be focused on restoring the aesthetic units, not on filling the defects. Sometimes the preservation of the aesthetic aspect interferes with the preservation of nose function and complete resection of the tumor, which is a challenge for the doctor to make the patient understand the prioritization of health over the aesthetic aspect and to help him to manage this situation without decreasing quality of life.

Conflicts of interest and sources of funding
The authors declare no conflict of interest.
This research received no external funding.

Authors' contribution
A.G. conceptualization and writing (original draft preparation), A.M.O. methodology and writing (review and editing), I.P.F. data curation and supervision. All authors have read and agreed to the published version of the manuscript.

Ethics approval and consent to participate
Approval of the local Ethics Review Board of Emergency University Hospital of Bucharest was obtained for the use of the patient data.

Patient consent for publication
Informed consent was obtained from all subjects involved in the study

Abstract: *Background: It is well known that patients with polycystic kidney disease (PKD) are at increased risk of developing cerebral aneurysms, however, this association has not been well studied for patients with polycystic liver disease (PLD). Material and methods: Cross-sectional descriptive study, which included 15 adult patients diagnosed with polycystic liver disease at the Gastroenterology and Hepatology Department of Fundeni Clinical Institute. Standard neurological exam and brain MRI were performed in all patients on a 1.5 Tesla MRI. Brain imaging protocol included T1/T2, T1SE, T2-FLAIR, DWI, SWI, 2D-TOF, 3D-TOF. Results: The majority of patients (93%) were females. The mean age was 53 ± 5 years old. Patients with AD-PKD and polycystic hepatic disease predominated (60%). Aneurysms were found in only one patient diagnosed with AD-PKD (in whom three aneurysms were described). The overall prevalence of cerebral aneurysms in our patient group was 7%. However, none of the patients with isolated PLD was found to have intracranial aneurysms. Other brain imaging abnormalities were frequent but nonspecific (mostly attributable to vascular-degenerative changes). Conclusions: Given these results, and due to the small number of patients in our study, it is hard to appreciate if polycystic liver disease is indeed associated with an increased risk of cerebral aneurysms.*

Keywords: *polycystic liver disease, cerebral aneurysm, brain MRI*

INTRODUCTION

Polycystic liver disease (PLD) is a genetic disorder characterized by the replacement of normal hepatic tissue with fluid-filled cysts. This is due to genetic mutations of the proteins that are involved in epithelial growth and transport of fluid in the liver [1]. Some authors have defined PLD by the presence of more than 10 cysts in the liver, while others have defined it as a liver containing over 20 cysts [2,3]. PLD can occur in isolation or can be associated with autosomal dominant polycystic kidney disease (AD-PKD), in which case patients present with cysts involving both the liver and the kidneys.

The latter combined form (AD-PKD and PLD) is more common, accounting for 80-90% of all patients with multiple liver cysts [4]. It is well-known that patients with PKD are at an increased risk of developing cerebral aneurysms [5,6], however, this association has not been well-studied for patients with PLD.

MATERIALS AND METHODS

We performed a cross-sectional descriptive study, in which we recruited 15 adult patients diagnosed with PLD at the Gastroenterology and Hepatology Department of Fundeni Clinical Institute. All patients were included on the liver transplantation waiting list (or have already benefited from liver transplantation). The evaluation comprised a standard neurological examination and electroencephalogram. Brain MRI was performed in all patients on a 1.5 Tesla MRI. Brain imaging protocol included T1/T2, T1SE, T2-FLAIR, DWI, SWI, 2D-TOF, 3D-TOF. To better characterize PLD, abdominal CT scans with contrast enhancement and volumetric assessment of the liver were performed in all patients. Laboratory workup included liver function parameters (albumin, total bilirubin, conjugated bilirubin, alkaline phosphatase, gamma-glutamyl transferase, alanine aminotransferase, aspartate aminotransferase, ammonia, blood coagulation tests), kidney function parameters (urea, creatinine, uric acid), complete blood count, inflammatory markers and tumoral markers (alpha-fetoprotein, CA 125, CA 15.3, CA 19.9, CEA). Liver disease severity was measured using the MELD score, while kidney function was measured using serum creatinine levels and creatinine clearance (Cockcroft-Gault Equation).

Patients were included only if an informed consent form was signed and if the inclusion and exclusion criteria were respected (see Table 1). The study protocol was approved by the Ethics Committee of Fundeni Clinical Institute.

Table 1: Inclusion and exclusion criteria used for patients in our study.

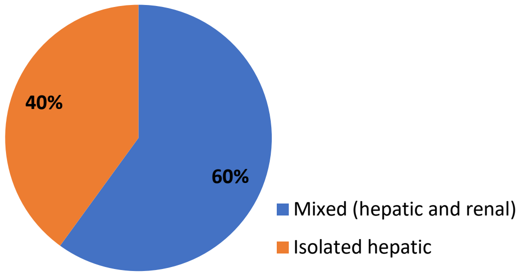
Exclusion criteria	Inclusion criteria
Patients diagnosed with other cystic lesions of the liver (e.g., Caroli disease)	Age > 18 years-old
Patients diagnosed with isolated polycystic kidney disease	Diagnosis of polycystic liver disease ± polycystic kidney disease

Relevant medical information (imaging results, laboratory test results) was accessed using the hospital's informatic system Hipocrate. The patient database was created with Microsoft Office 365.

RESULTS

93% of the patients were females (n=14). The mean age of patients was 53 ± 5 years old. The mean age at the time of PLD diagnosis was 38 ± 12 years old. The majority of patients (60%) had PLD associated with AD-PKD (see Figure 1). The mean hepatic volume as assessed by abdominal CT volumetry was 7406.38 ± 2939.83 cm3. The mean MELD score was 8 ± 2 points (patient range: 6-12 points). The mean creatinine level was 1.0 ± 0.3 mg/dL (patient range: 0.68 – 1.72 mg/dL). Only two patients had serum creatinine above the upper normal limit and were diagnosed with chronic kidney disease in the setting of polycystic kidney disease. The mean level of alkaline phosphatase was 102 ± 47 units/liter, while the mean level of gamma-glutamyl transferase was 70 ± 70 units/liter. Two patients benefited from a kidney transplant in the past, and one of them received a liver transplant as well.

Figure 1: Proportion of patients with isolated versus mixed hepatic-renal polycystic disease



Clinical neurological exam was normal in almost all patients. One patient was deaf-mute, another patient had a positive left-sided Lasègue's sign and diminished Achilles reflexes, and another patient had diminished Achilles reflexes. Apart from these findings, all neurological examinations were unremarkable. Regarding brain MRI abnormalities, unruptured cerebral aneurysms were found in only one patient (in whom three aneurysms were described). However, it should be mentioned that this patient was diagnosed with autosomal-dominant polycystic kidney disease, and not with isolated polycystic liver disease. Of the three aneurysms, the first two were saccular: one measured 3 mm and involved the M1 segment of the left middle cerebral artery, and the other one measured 9.7 mm and involved the M1 segment of the right middle cerebral artery. The third aneurysm was fusiform, had a diameter of 5.5 mm, and involved the right vertebral artery. The overall prevalence of cerebral aneurysms in our patient group was 7%.

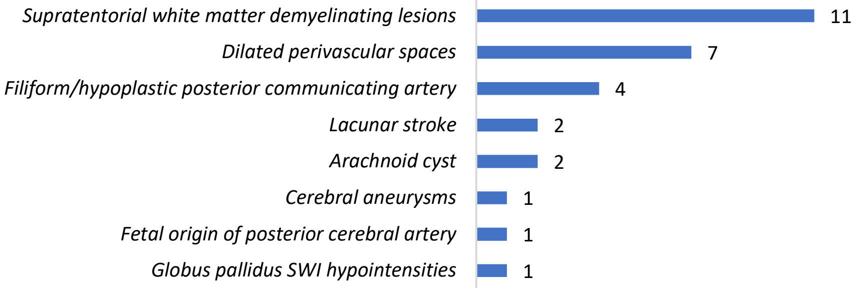
Nonspecific supratentorial demyelinating lesions were described in the majority of patients (73%) (see Figure 2). More than a quarter of patients presented with filiform (hypoplastic) posterior communicating arteries. Dilated perivascular spaces were described in 47% of patients (n=7).

DISCUSSION

The prevalence of isolated polycystic liver disease (PLD) varies in the literature. While autosomal dominant polycystic kidney disease (AD-PKD) affects up to 0.2% of the population, the frequency of isolated PLD is much lower (under 0.01%) [7]. Some authors have cited a prevalence of 1 up to 9 cases per 100 000 persons for isolated PLD [8].

On the other hand, the hepatic cystic disease is one of the main extrarenal manifestations of AD-PKD, and its prevalence is age-related, increasing from 20% in the third decade to 70% in the seventh decade [9]. The prevalence of hepatic cysts in patients with AD-PKD may be as high as 83% (if properly sought by MRI), as was highlighted in one study [10]. The number and size of hepatic cysts have been shown to correlate not only with the age of patients but also with female sex, history of pregnancy, the severity of renal cystic disease, and decreased renal function (as measured by the creatinine clearance) [11].

Figure 2: Imaging findings in patients with PLD. Note that cerebral aneurysms were detected in only one patient



When looking at unruptured cerebral aneurysms, we find an overall prevalence in the general population of approximately 3%, and only a fraction of them progresses toward rupture (with subsequent subarachnoid hemorrhage) [12]. In a systematic review that analyzed 23 studies (comprising more than 56000 patients), the prevalence of intracranial aneurysms varied considerably according to study design and study population, from 0.4% in retrospective autopsy series, to 3.6% in prospective autopsy series, to 3.7% in retrospective angiography series and up to 6% in prospective angiography series [13]. However, when all available evidence was taken into account (including factors that overestimate or underestimate the risk), a frequency of about 2% for cerebral aneurysms was calculated in adults without risk factors for subarachnoid hemorrhage.

The prevalence of intracranial aneurysms in patients with AD-PKD is higher than in the general population [14,15]. Perrone et al mentioned a frequency of about 10% in asymptomatic patients and up to 25% in patients with a family history of intracranial aneurysms or subarachnoid hemorrhage. Likewise, Sanchis et al noted a prevalence of 9% for cerebral aneurysms after evaluating 812 patients with AD-PKD using screening with MR angiography. In another paper, in which 355 patients with AD-PKD underwent screening by 3D-TOF MR-angiography, the prevalence of intracranial aneurysms was found to be 12.4% [16].

Data regarding the frequency of cerebral aneurysms in patients with isolated PLD are lacking and only a few published papers have addressed this issue. In one study, an asymptomatic cerebral aneurysm was found in one out of the 10 patients with PLD who received screening studies of the cerebral vessels. [17]. Schievink et al described an instance of a familial association between PLD and cerebral aneurysms, in which a father with isolated PLD died of a ruptured cerebral aneurysm, while two of his six children also presented brain aneurysms (one of whom was diagnosed with isolated PLD) [18]. There is also a published case of a ruptured cerebral aneurysm associated with bilateral carotid dissection in a normal-weight woman who presented upon clinical examination with an enlarged abdomen. Abdominal CT highlighted a massively enlarged polycystic liver (with only a few cysts in the kidneys), while subsequent genetic analysis was positive for homozygote mutations in the PKD1 gene (for AD-PKD) and ADPLD gene (for PLD) [19]. Aneurysms situated in other parts of the circulatory system have also been described concerning PLD. Such is the case published about a 51 years-old male with PLD, who was discovered to have bilateral popliteal aneurysms [20]. The clinical features of patients with isolated PLD have been compared to those of patients with polycystic liver in the setting of AD-PKD. Patients with isolated PLD have greater numbers and larger sizes of cysts but have a more benign disease course and less associated morbidities than patients with AD-PKD [21]. It remains to be seen if this last statement can be extrapolated to the risk of intracranial aneurysms. Given that their frequency increase with age (both in the general population and in patients with AD-PKD), large prospective studies are needed to assess the prevalence of intracranial aneurysms in patients with isolated PLD.

The rupture rate of cerebral aneurysms in patients with AD-PKD appears to be similar to that of the general population [22]. In the review performed by Cagnazzo et al, the rupture rate, growth rate, and incidence of new aneurysm formation were 0.4% per patient-year, 0.4% per patient-year, and 1.4% per patient-year, respectively.

The main risk factor for the presence of unruptured intracranial aneurysms is a positive family history of intracranial aneurysms. However, most cases of ruptured cerebral aneurysms occur in the absence of a positive family history. In a study discussing the necessity of screening for cerebral aneurysms in patients with AD-PKD, about one-third of nephrologists were in favor of systematic screening for all patients with AD-PKD [23]. However, after reviewing 15 studies (comprising almost 1500 patients with AD-PKD), Zou et al concluded that screening should be recommended only for patients with a positive family history of hemorrhagic stroke or intracranial aneurysm and if they originate from China, Japan, and Europe (since the studies from these countries reported a higher prevalence of aneurysms). The calculated incidences of aneurysm rupture, aneurysm growth, and new aneurysm formation were 0.13%, 1.84%, and 0.57%, respectively [24]. Poor outcomes among treated aneurysms were seen in one study only with the ruptured presentation and did not differ significantly between treatment modalities (open surgery versus endovascular approach) [25].

CONCLUSIONS

In our study, cerebral aneurysms were found in only one patient, who was diagnosed with autosomal-dominant polycystic kidney disease. None of the patients with isolated polycystic liver disease was found to have intracranial aneurysms.

Given these results, and due to the small number of patients in our study, it is hard to appreciate if polycystic liver disease is indeed associated with an increased risk of cerebral aneurysms. Other brain imaging abnormalities were frequent but nonspecific (mainly attributable to vascular-degenerative changes).

Abstract: *A rise in mortality due to fungal infections in an immunocompromised population has been observed lately. Nowadays, due to increased fungal infections, the limitations encountered in their treatment like resistance, side-effects, and high toxicity, the rising prescription and overuse of conventional antifungals all stimulate a search for alternative natural drugs therefore we are in dire need of natural newer strategies that involve reliable agents for the treatment of fungal diseases such as essential oils are known for their anti-microbial properties and are multi-component. Materials & Methods: Soil samples (66 samples) were collected from different agricultural fields and animals habitat of Saharanpur (U.P.) Isolation of keratinophilic fungi was carried out by the hair-baiting technique. Extraction of Mentha piperita & Cinnamonum vernum essential oil was carried out by hydrodistillation method and the chemical composition of both extracted essential oils was determined by Gas Chromatography-Mass Spectrophotometry. Antimycotic studies of essential oils were done by the standard disc diffusion method. Results & Discussion: In the present study, the antifungal potential of Mentha piperita & Cinnamonum vernum essential oils were evaluated against three human pathogenic fungi isolated from the soil of agricultural field and animals habitat of Saharanpur (U.P.) i.e Trichophyton mentagrophytes, T.tonsurans, and T.equinum. The chemical composition of Mentha piperita & Cinnamonum vernum EO was analyzed by GC-MS. Menthol (53.28%) was the major compound of the Mentha piperita EO followed by Menthyl acetate (15.1%) and Menthofuran (11.18%). Major constituents of Cinnamonum vernum EO were linalool (8%), (E)-cinnamaldehyde (7.2%), β-caryophyllene (7.4%), eucalyptol (6.4%), and eugenol (5.6%). Conclusion: Essential oils of Mentha piperita & Cinnamonum vernum have been found to have remarkable & excellent antifungal activity against these pathogenic fungi. Present findings conclude that natural products like plant-derived EOs instead of chemotherapy and the emergence of resistance to antifungal drugs can be regarded as an environmental safety mode of disease control against pathogens.*

Keywords: *essentials oils, antimicrobial, drug, resistance, natural, products*

INTRODUCTION

Keratinophilic fungi are a group of microorganisms that can decompose keratin remains in the environment and are pathogenic to humans and animals. The soil that is rich in keratin materials is most conducive for the growth and occurrence of keratinophilic fungi distribution is variable with the environment and depends on different environmental factors such as humans' and animals' presence. Keratinophilic fungi include a variety of filamentous fungi mainly comprising hyphomycetes and several other taxonomic groups [1-2]. Dermatophytes cause humans and animal mycoses and thus have drawn the attention of medical and veterinary epidemiologists. The majority of dermatophytes can live saprophytically and keratinophilic fungi can be considered as a potential pathogen [3]. They occur in many natural and man-made habitats. Keratinophilic fungi are unique in the sense that they require and utilize keratin for growth [4-5]. Studies on keratinophilic fungi are now of considerable significance for their important role in the breakdown of keratinous debris of animals and man in nature and they have a worldwide distribution [6,7]. Studies have shown that soils are important sources of dermatophytes and keratinophilic fungi [8-10]. In the past two decades, the emergence of resistance to various antifungal drugs has accelerated dramatically. Azole-resistant Candida and Aspergillus species are the top pathogens responsible for nosocomial or food-borne infections [11,12]. In addition, the formation of biofilms by Candida species has raised concerns due to their increased resistance to antifungal therapy, and protects the microbial cells within biofilms from the host immune defenses [13,14]. Moreover, EOs especially those with known antibacterial effects have the potential to be used in the food industry as preservatives and to increase the shelf life of products. Therefore, determining the antimicrobial properties of EOs might help to overcome microorganism resistance to antibiotics. The chemical composition of aromatic plants depends largely on individual genetic variability and different plant parts. The presence and concentration of certain chemical constituents of EOs also fluctuate according to the season, climatic condition, and site of plant growth [15]. A review of the literature reveals that many essential oils acquire antifungal activity [16-19]. The development of antifungal resistance is complex and depends on multiple hosts and microbial factors [20]. According to Moreira et al, lipophilic compounds of the oils bond the phospholipid bilayer of the cell membrane increasing its permeability and spreading out the intracellular contents or damaging the enzymatic system of the cell [21-22]. M. piperita oil is one of the most popular and widely used essential oils, mostly because of its main components, Menthol, and menthone [23]. Previous studies have shown antiviral, antibacterial, antifungal, antibiofilm formation, radio-protective, angioedema, analgesic, and antioxidant activities of the EO [24-26]. Cinnamon is a good source of the powerful antioxidant manganese. Therefore, much attention has been paid to the discovery and development of new antimicrobial agents that might act against these resistant microorganisms, and cinnamon could be an interesting candidate [27-28]. Concerning volatile components, the chemical composition of cinnamon essential oils depends on the part of the plant from which they are extracted [29-31]. The presence and concentration of certain chemical constituents of EOs also fluctuate according to the season, climatic condition, and site of plant growth [15,32]. The objective of this work was to evaluate the antifungal efficacy of Mentha piperita & Cinnamonum vernum EOs against drug-resistant three widely pathogenic fungal strains that cause superficial skin infections in humans and trying to find more safely hygienic natural plant products. The goal of this study was to investigate the chemical composition and in vitro antifungal activities of essential oils in the leaves of M. piperita & C. vernum.

MATERIALS AND METHODS

Collection of Soil Samples

Sixty-six soil samples were collected from different agricultural fields and animals habitat of Saharanpur (U.P.) India. For this present study, different soil samples were collected in sterile polyethylene bags and brought to the laboratory for further microbiological analysis. Keratin substrates (Ks) were collected from different sources such as chicken feathers, buffalo hairs, goat hairs, dog hairs, pig hairs, ship hairs, and horse hairs in clean sterilized plastic bags and transferred to the laboratory. Samples were transmitted to the laboratory as early as possible for further analysis like pH, temperature, humidity, salinity, and total dissolved solids.

Isolation of keratinophilic fungi by Hair Bait Technique

Isolation of keratinophilic fungi was done using the hair bait technique (Vanbreuseghem, R. 1952) [33]. Moist chambers were prepared using sterile soil samples. 2-3 cm short strands of sterilized defatted baits were spread over soil samples. 10-15 ml of sterile water was added to the soil to facilitate the germination of fungal spores. Petri dishes were then incubated at room temperature at 28◦C for 15-20 days. Plates were examined periodically for the development of mycelium.

Identification of Keratinophilic fungi

Every single fungal colony was taken from the mixed culture. The pure culture was developed by repeated subculturing which was transferred to an agar slant and subcultured and then stored at 4°Ċ temperature. The fungal colonies were identified by microscopic and macroscopic characteristics. The macroscopic examination of fungi was characterized by duration of growth, surface morphology, and pigment production on the reverse and microscopically, the isolated fungi were stained with Lactophenol cotton blue staining and observe under the microscope at high power of the objective lens.

Gas chromatography Mass Spectrometry (GC-MS) analysis of M. piperita and C. vernum essential oils.

Quantitative and qualitative analyses of the essential oils were performed using a GC-MS apparatus. The analysis was performed with an Rtx 5 MS column. For the GC-MS detection, an electron ionization system with an ionization energy of 70eV was used. Nitrogen gas was used as carrier gas with a flow rate of 1.21 ml/min. The column was raised from 50ºC to 320ºC at a rate of 3ºC/min. The relative percentage of the oil constituents was expressed as a percentage by peak areas and the identification of oil components was based on their retention time with available literature values.

Antimycotic Studies of Essential Oils against Selected Fungi by Disc Diffusion

Oil was screened for its antifungal activity against T. mentagrophytes, T. equinum, and T. tonsurans by disc diffusion method [34]. Standard size Whatman no. 1 filter paper discs 6.0 mm in diameter, sterilized by dry heat at 140°C in an oven for one hour were used to determine antifungal activity. SDA medium for the disc diffusion test was prepared. After sterilization, it was poured into sterilized Petri plates and allowed to solidify. Then one-day old fresh culture of isolated fungi was used for inoculums preparation. A suspension was just turbid (~0.5 McFarland standard) by visual inspection and was prepared by suspending fungus in 0.9% NaCl solution and the homogeneous suspension was used for inoculation. Using a sterile cotton swab, fungal cultures were swabbed on the surface of sterile Sabourauds Dextrose Agar plates. Sterilized filter paper discs were soaked in neat, undiluted (100%, 75%, 50%, 25%) concentrations of oils. Using ethanol-dipped and flamed forceps, oil-saturated discs of 100%, 75%, 50%, and 25% concentration were aseptically placed over Sabourauds dextrose agar plates seeded with the respective test microorganism. The antibiotic discs of Clotrimazole and Ketoconazole (10 mcg per disc) were also aseptically placed over the seeded Sabouraud's dextrose agar plates as a standard drug for comparison of antifungal activity with essential oils. The plates were incubated at 28ºC for 48-72 hours. The diameter of the inhibition zones was measured in mm and the activity index was calculated based on the size of the inhibition zone. Three replicates were kept in each case and average values were calculated.

RESULTS

The present study reported that out of sixty-six soil samples collected, three species of keratinophilic fungi were predominantly isolated from different animal habitats and agricultural fields with different keratin substrates. These habitats contain lots of keratin debris. In the present work, T. mentagrophytes, T. tonsurans, and T. equinum were isolated predominantly from the agricultural and animal habitat soils of Saharanpur (U.P) and also found the main etiological agent of zoonotic dermatophytosis in the investigated area. Macroscopic & Microscopic characteristics of isolated fungi are shown in Table.1. Various earlier workers reported the diverse population of keratinophilic fungi and dermatophytes from Indian soil [35,36]. The high prevalence of keratinophilic fungi from the soil of Saharanpur is due to buffalo hairs, human hairs, and dog hairs which come to the soil either as dead or dropped off serve as substrates, and are subjected to microbial decomposition. The present study indicates that the diverse existence of keratinophilic fungi in the soil of Saharanpur plays a major role in bioremediation in the natural environment. The present study coincides with other workers who also reported diverse soil habitats have been screened from different countries Brazil, Kuwait, Iran, and India indicating that these groups of fungi are distributed worldwide [37-39]. In urban areas, where there are high concentrations of people and animals, soil rich in organic matter may constitute a permanent or occasional reservoir for fungi and during this fungi can be a potential source of skin infection for animals and humans. These animals serve as reservoirs of zoophilic dermatophytes and their zoonotic infections have considerable importance [40-42]. Sandpits are thought to play a role in the epidemiology of human and animals mycoses and reported special care needs to be paid to identify potential pathogenic fungal species such as species from Fusarium, isolated from soil samples of recreational parks and in all elementary schools [43]. Some workers reported that when infections due to other opportunistic fungal agents occur can lead to very unfavorable and even serious outcomes of infection by fungi [44].

Table 1: Macroscopic & microscopic characteristics of isolated fungi

S. No	Isolated Fungi	Macroscopic Characteristics	Microscopic Characteristics
1	*Trichophyton tonsurans*	Colonies on Sabouraud's Dextrose Agar at 28°C grow moderately and the color of the colony is initially white than creamy yellow rose at age with conidial production. Suede-like with radial folds sometimes powdery or velvety. The reverse is a pale lemon yellow to mahogany brown may dark diffusing in the agar.	Many pyriform microconidia on stalks ballon forms. Rare distorted macroconidia. Hyphae are relatively broad irregular, and much branched with numerous septa. Microconidia are varying in size and shape from long clavate to broad pyriform is borne right.
2	*Trichophyton mentagrophytes*	Colonies on Sabouraud's Dextrose Agar at 28°C grow moderately and velvety, flat, and thin with powder and pale powder dry & white powder in color.	Round microconidia in grape-like clusters, Spiral hyphae, and macroconidia narrowly attached to hyphae.
3	*Trichophyton equinum*	Growth rate moderately rapid texture suede-like to downy flat. Thallus color cream to pale yellow deep to pinkish or brown is in the center. Reverse deep yellow becoming red-brown or dark pink may produce brown soluble pigment.	Pyriform microconidia lateral may be produced on stalks. Rare club-shaped macroconidia smooth thin-walled.

The leaves of Mentha piperita and Cinnamonum vernum were collected from Saharanpur (U.P) and essential oil was extracted by Clevenger apparatus based on the hydro-distillation method as shown in Figures 1 and 2. Hence, antimycotic studies and chemical composition of essential oils of Cinnamon & Peppermint were carried out against selected fungi to eco-friendly control fungal infections. In the present study, thirteen (13) compounds representing 99.37% area of the oil, were identified. The qualitative and quantitative compositions of the EO of M. piperita by GC-MS analysis and antifungal activity carried out by disc diffusion method are presented in Tables 2, 3, and Figure 3.

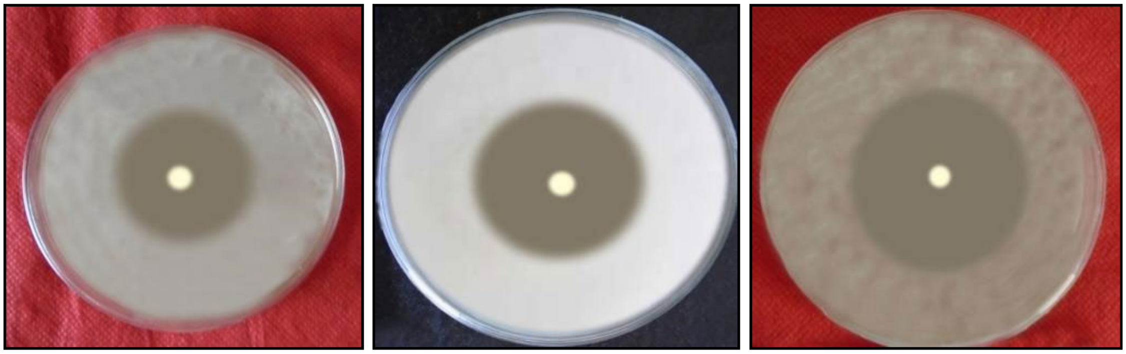
Figure 1: Mentha piperita (Peppermint oil)

M. Peppermint

Figure 2: Cinnamon oil (Cinnamomum Verum)

Cinnamon oil

Figure 3: Antidermatophytic activity of M.piperita essential oil at 100% concentration against selected fungal strains



(A) T. equinum (B) T. mentagrophytes (C) T. tonsurans

GC/MS analyses showed that the main constituent of the M. piperita EO was Menthol (53.28%) followed by Menthyl acetate (15.1%) and Menthofuran (11.18%). The compositions of the EOs might be affected by the developmental stages of the plant.

Some authors reported alpha terpinene as the dominant component of M. piperita EO (19.7%) while other previous studies identified Menthol as one of the main constituents of the Eos [23,45]. The higher concentration of Menthol in this study may reflect variations due to the geographical location from which the plants were collected.

In this study, the EOs of Mentha piperita exhibited strong antimycotic activities against T. mentagrophytes (60 mm), T. equinum (67 mm), and T. tonsurans (50 mm) at 100% concentration of pure essential oil than standard drugs.

Table 2: Chemical components (%) of the essential oils distilled from Mentha piperita

Compounds	RI	% oil
α-Pinene	930	0.32
Sabinene	970	0.26
β-pinene-1	978	0.58
β-pinene-2	1035	6.69
Ci$-sabinene hydrate	1072	0.50
Menthone	1155	2.45
Menthofuran	1168	11.18
Neomenthal	1166	2.79
Menthol	1178	53.28
Neomenthy acetate	1274	0.65
Menthyl acetate	1298	15.10
Isomenthyl acetate	1308	0.61
β -Bourbonene	1389	0.37

Table 3: Antifungal activity of Mentha piperita oil against selected isolated fungal strains

S. No	Oil	Test strain	Concentration of oil	IZ of sample
1.	*Mentha piperita Oil (Peppermint oil)*	*T. mentagro-phytes*	100 %	60 mm
			75 %	50 mm
			50 %	29 mm
			25 %	12 mm
2.		*T. tonsurans*	100 %	67 mm
			75 %	40 mm
			50 %	30 mm
			25 %	15 mm
3.		*T. equinum*	100 %	50 mm
			75 %	39 mm
			50 %	29 mm
			25 %	15 mm

IZ = Inhibition zone (in mm) including the diameter of the disc (6 mm).

IZ of Ketoconazole & Clotrimazole (10 mcg/disc) is 32 mm & 30 mm against T. mentagrophytes

IZ of Ketoconazole & Clotrimazole (10 mcg/disc) is 28 mm & 25 mm against T. tonsurans

IZ of Ketoconazole & Clotrimazole (10 mcg/disc) is 24 mm & 22 mm against T. equinum

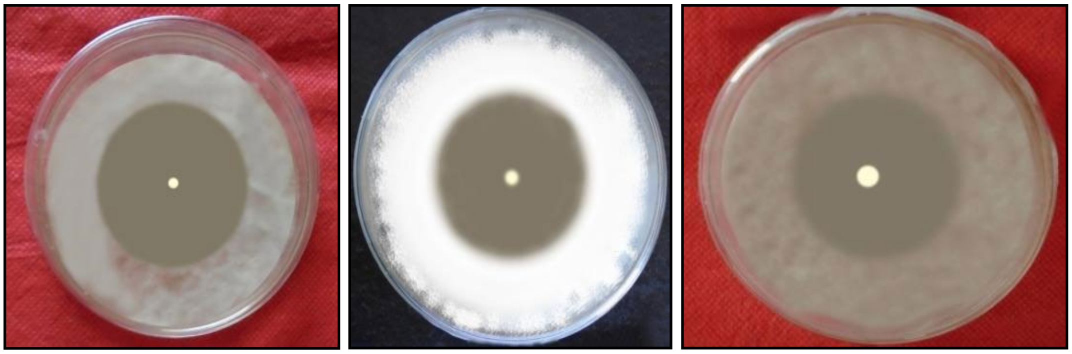
Similarly second oil i.e. Cinnamonum verum, chemical constituents were identified by GC-MS analysis resulting in the identification of ten (10) chemical compounds for C. vernum essential oil, as indicated in Table 4 and Figure 4.

(E)-cinnamaldehyde (7.2), linalool (8.00%), β-caryophyllene (7.40%), eucalyptol (6.40%), and eugenol (5.60%) were the main components of the C. vernum essential oil. The other important constituents were p-cymene (1.90%), α-humulene (1.70%), δ-cadinene (1.40%), α-pinene (1.30%), and limonene (1.20%). Following our results, several studies have reported that cinnamaldehyde is the major chemical compound of C. zeylanicum bark essential oil [46,47].

Table 4: Chemical components (%) of the essential oils distilled from Cinnamonum vernum

Compounds	RI	% oil
E-cinnamaldehyde	15.22	7.2
α-Pinene Linalool	5.66	1.3
Linalool	9.86	8
β-Caryophyllene	18.58	7.4
Eucalyptol	8.08	6.4
Eugenol	16.90	5.6
α-Humulene	19.47	1.7
δ-Cadinene	20.97	1.4
p-Cymene	7.82	1.9
Limonene	7.93	1.2

Figure 4: Antidermatophytic activity of C.vernum essential oil at 100% concentration against selected fungal strains



(A) T. equinum

(B) T. mentagrophytes

(C) T. tonsurans

Antimycotic activity of C. vernum essential oil was also evaluated by disc diffusion method and found excellent inhibition of zone at 100% concentration of pure essential oil against T. tonsurans (60 mm), T. mentagrophytes (59 mm) & T. equinum (58 mm) as compared to standard antifungal drugs i.e. Ketoconazole & Clotrimazole (Table 5).

Table 5: Antifungal activity of Cinnamonum vernum oil against selected fungi

S. No	Oil	Test strain	Concentration of oil	IZ of sample
1.	*Mentha piperita Oil (Peppermint oil)*	*T. mentagro-phytes*	100 %	59 mm
			75 %	50 mm
			50 %	30 mm
			25 %	20 mm
2.		*T. tonsurans*	100 %	60 mm
			75 %	46 mm
			50 %	31 mm
			25 %	19 mm
3.		*T. equinum*	100 %	58 mm
			75 %	45 mm
			50 %	31 mm
			25 %	19 mm

IZ = Inhibition zone (in mm) including the diameter of the disc (6 mm).

The traditional use of plants as medicines provide the basis for indicating which essential oils may be useful for specific medical conditions. It is important to investigate scientifically those plants which have been used in traditional medicines as potential sources of novel antimicrobial compounds. The present findings are similar to Wuthi-udomlert et al. (2000) who reported the antifungal activity of turmeric oil against 29 clinical strains of dermatophytes and in the screening of turmeric oil, the diameter of the inhibition zone was found to vary from 26.1 mm to 46 mm against 29 clinical strains of dermatophytes [48].

Numerous scientific studies proved the inhibitory effect of essential oils against different fungi [49]. It is important to analyze the plants which have been used in the medicines as a potential source of normal antimicrobial compounds. The present work coincides with the work of Sharma et al. (2011) who also reported the additive and inhibitory effect of Curcuma longa (Turmeric) and Zingiber officinale (Ginger) essential oils against dermatophytes causing superficial skin infections [50]. The use of essential oils in the treatment and prevention of infection has been in demand in the field of research from the past. Natural products have served as a research resource for most drugs, providing a basis for chemical research and the discovery of new drugs [51].

Several reasons have been offered to explain the success of natural products, among them are their great chemical diversity, the effects of evolutionary pressure in creating biologically active molecules, and the structural similarity of protein targets in different species, among others [52]. The treatment of fungal disease is limited and part of the reason is due to the limited spectrum of the currently antifungal drugs and the expensive treatment particularly due to the need for prolonged therapy. Jayaprakasha et al., (2003) also reported some alternative therapies including natural products are necessary to control fungal infections [53].

Various workers have reported that due to the high volatility and lipophilicity of the essential oils, they are readily attached to penetrate into the cell membrane to exert their biological effect. Ali & Ali (2019) in Saudi Arabia investigate the antifungal activity of plants from the Jeddah region (A. indica, Z. spina-christi, and O. europaea), P. dactylifera seed, neem oil, and other oils [54]. Another interesting investigation reports the antibacterial activity of cinnamon bark essential oil and its main constituents, trans-cinnamaldehyde and eugenol against Cronobacter sakazakii and C. malonaticus, which are opportunistic pathogens that cause infection in children and immunocompromised adults. Kizil et al (2010) reported the EOs exhibited fungistatic and fungicidal activities against both the standard and clinical strains of Candida species at concentrations ranging from 0.5 µL/mL to 8 µL/Ml [55].

According to the study of Saharkhiz et al, (2010), essential oils killed the standard strain of C. neoformance is a well-known primarily opportunistic pathogen that produces chronic and life-threatening meningitis at a concentration of 4 µL/mL [56]. The antifungal activities of the essential oils (EOs) of Acantholippia seriphioides, Artemisia mendozana, Gymnophyton polycephalum, Satureja parvifolia, Tagetes mendocina, Lippia integrifolia, collected in the Central Andes area, Province of San Juan, Argentina, were investigated against M. gypseum, T. mentagrophytes and T. rubrum and were inhibited by the EOs of G. polycephalum, L. integrifolia, and S. parvifolia, with minimum inhibitory concentrations (MICs) between 31.2 and 1000 µg/ml.

This study shows that these Central Andean area species might be used to treat superficial fungal infections [57]. The study of Agarwal et al. (2008) and Saharkhiz et al. (2010) found that the formation of biofilm by C. albicans was inhibited completely at a concentration of up to 2 µL/mL in a dose-dependent manner [56,58]. Shiming et al (2006) reported antifungal mechanism of essential oils, inhibits the synthesis of ergosterol in fungal and cholesterol in mammalian cells [59]. The present results showed the excellent antidermatophytic efficacy of M.piperita and C.vernum against T. mentagrophytes. T. tonsurans and T. equinum as compared to standard antifungal drugs and can be used to control the superficial fungal infections of the skin as an eco-friendly agent and to combat the mechanism of antimicrobial drug resistance.

The tested Essential oil in the present study was rich in Menthol. It has been shown that this phenolic monoterpene has a hydroxyl group around the phenolic ring and exhibits its antimicrobial activity through the disruption of the cytoplasmic membrane due to the main characteristics of EOs is their hydrophobicity, which enables their incorporation into the cell membrane. [60,61]. The great importance of natural products in developing new therapeutic tools is evident. In this aspect, medicinal plants and their derivatives are important for pharmacological research and drug development. Special attention has been directed to natural derivatives, based on the knowledge of antifungal compound production in nature.

CONCLUSIONS

The polluted area of agricultural fields of soil is a dynamic medium in which a large number of keratinophilic and non-keratinophilic fungi live in close association. Some keratinophilic fungi are pathogenic to man and animals. Dermatophytic infections are highly common and endemic diseases in developing countries due to poverty, improper health facilities, illiteracy, and other poorly developed diagnostic techniques. Also, some microorganisms are resistant to newer or modern antifungal synthetic drugs and in some severely immunosuppressed patients. M.piperita and C.vernum essential oils can be suggested as an alternative to synthetic antibiotics, especially for the treatment of antibiotic-resistant infections. These EOs can also be considered for developing products to control fungal infections. Thus, there is a need for an alternative therapy that is safe, cheaper, economical & easily available so a wide range of essential oils from plants are still unexplored for their antifungal activity. Hence, the present study concludes to explore new antifungal agents alternative to synthetic drugs for the treatment of dermatophytic & other fungal diseases. This research study will be beneficial for human health, the human economy, environment safety, and antimicrobial drug resistance for proper and timely treatment of fungal infections in immunocompromised patients.

Acknowledgments

The authors are highly thankful to BISR for GC-MS of essential oils.

Abstract: *Since vitamin D is synthesized from cholesterol, it is claimed to be associated with insulin resistance, suggesting that there may be an association between vitamin D glucose and lipids. For this reason, we aimed to investigate a relationship between vitamin D and biochemical parameters, including glucose and lipids. This cross-sectional study included 198 patients .admitted to the family medicine outpatient clinic between June and December 2016. There was no significant correlation between vitamin D and serum glucose, total cholesterol, triglyceride, HDL cholesterol, LDL cholesterol, calcium, magnesium, sodium, TSH, and body mass index values in both men and women. There was a correlation between vitamin D and total cholesterol and LDL cholesterol levels in the younger subjects below 41 years (p=0.002). Regression analysis with other variables showed no statistical significance between vitamin D levels on LDL-C levels (P=0.309). Despite previous studies, our study did not confirm the effects of vitamin D on serum glucose, lipid, calcium, and other biochemical parameters. However, these results suggest that the standard up-to-date literature showing the relationship between vitamin D and various metabolic and hormonal disorders may need to be confirmed by new large-scale studies.*

Keywords: *vitamin D; glucose; lipid profile; calcium; biochemical parameters*

INTRODUCTION

The prevalence of vitamin D deficiency is reported to be between 30% to 50% globally in the general population. Similarly, in Turkey, this ratio was found to be 51% in Ankara and 46.9% in İzmir [1-3]. Also, in a study conducted among female university students in Istanbul, vitamin D. levels were found below normal values in 92.4% of the participants [4]. A study conducted in Konya detected vitamin D deficiency in 88,4% of the patients admitted to the family medicine outpatient clinic for any reason [5].

Vitamin D is usually found in foods from animal sources in the form of cholecalciferol and small amounts in plant sources in the form of ergosterol. It is primarily synthesized in the skin under the influence of sunlight [6,7]. Cholecalciferol is synthesized in the epidermis from 7-dehydrocholesterol by the effect of ultraviolet B rays or can be taken with food. First, it transforms into 25-hydroxycholecalcidiol in the liver and then into 1.25-hydroxycholecalcitriol, the active form, in the kidneys [8]. Vitamin D deficiency paves the way for diseases such as rickets in children and osteomalacia in adults [9,10]. It has been suggested to prevent colorectal and prostate cancers and the formation of disorders such as prediabetes and metabolic syndrome by decreasing insulin resistance when taken at high doses [11,12]. In addition, it has been stated that vitamin D deficiency may affect cardiac functions such as diastolic function and aortic elasticity [13].

Vitamin D affects calcium absorption and metabolism by regulating receptor-mediated gene expression [14]. In addition to intestinal and bone tissue, vitamin D receptors are found in many tissues, including the brain, heart, stomach, pancreas, skin, gonads, and T and B lymphocytes. It is accepted that Vitamin D inhibits the proliferation of both normal and hyperproliferative cells and promotes the maturation of these cells through its receptors [7]. Controversial results have been reported on the effects of vitamin D other than calcium metabolism; while some studies suggest a positive effect on the lipid profile, some found no association between vitamin D and lipid parameters [15,16].

We hypothesized that because vitamin D is synthesized from cholesterol and has numerous receptors in tissues, it might interact with biochemical parameters, including glucose and lipids. Therefore, we aimed to investigate the relationships between vitamin D levels and other biochemical parameters, including glucose and lipids.

MATERIALS AND METHODS

Study Design

This study is a cross-sectional study. The sample size was calculated to be at least 162 according to the formula n = t2pq/ d2. In determining the sample size, the p-value was accepted as 0.12, the q-value was 0.88, the d-value was 0.05, α error level was 0.05, and the t-value according to the error level was 1.96.

Population selection

The study included one hundred ninety-eight patients selected from the patient records who applied to the family medicine outpatient clinic for general control between May and October 2016. Individuals who did not use any medication and were found to be healthy were included in the study. Patients with previously defined diseases, such as depression, anxiety, hypertension, diabetes, hyperlipidemia, thyroid dysfunction, vitamin B12 deficiency, liver disease, and kidney disease, were excluded from the study. Demographic data, including age, sex, body mass index (BMI), and biochemistry laboratory parameters, were obtained from patient records. The subjects were then divided into two groups for age using the simple arithmetic mean method.

Statistical analysis

The data were analyzed using SPSS software (PASW Statistics for Windows, Version 16.0. Chicago: SPSS Inc.). Categorical data are expressed in numbers and percentages. Numerical data were expressed as means and analyzed by the Mann-Whitney U test in independent groups. Spearman Correlation analysis was used for correlation analysis. The linear regression test was used to show any relationship between the parameters. The Kolmogorov-Smirnov test was used to determine homogeneity for the variants.

Ethical Considerations

Ethical approval was obtained from the İstanbul Training Research Hospital Clinical Research Ethics Committee (Decision no. 09.08.2019, 1944).

RESULTS

A total of 198 patients aged 18-75 years (41.81±13.43), 71.2% female (141) and 28.8% male (57), were included in the study. The mean age of women was significantly lower than that of men (45.70 versus 40.20). Serum vitamin D, Body Mass Index (BMI), glucose, triglyceride, calcium, and magnesium levels were lower, and serum HDL cholesterol (HDL-C) levels were significantly higher in females compared to males (Table 1). Vitamin D levels had no significant correlation between serum glucose, total cholesterol, triglyceride, HDL-C, LDL cholesterol (LDL-C), calcium, magnesium, sodium, and TSH levels, and BMI values in both groups (Table 2).

Table 1: Comparison of serum vitamin D, glucose, lipid, calcium, magnesium, sodium, TSH, and BMI parameters between women and men

Parameters	Min-Max	Total	Women	Men	Z	p
		Mean ± SD (n)				
Vitamin D (ng/ml)	4.4-89.9	18.49±11.01(198)	16.92±9.67(141)	22.38±13.28(57)	-3.87	0.001*
Age (years)	18-75	41.81±13.43(198)	40.20±13.30(141)	45.79±13.04(57)	-2.88	0.004*
Glucose (mg/dl)	72-188	96.10±15.20(198)	93.28±11.32(141)	103.07±20.58(57)	-4.24	0.001*
Cholesterol (mg/dl)	99-331	207.72±44.07(198)	209.12±44.21(141)	204.25±43.91(57)	-0.54	0.585
Triglyceride (mg/dl)	29-417	118.78±65.32(198)	103.91±46.17(141)	155.56±88.02(57)	-3.93	0.001*
HDL-C (mg/dl)	28-104	53.54±12.63(198)	56.75±12.72(141)	45.60±8.18(57)	-6.18	0.001*
LDL-C (mg/dl)	44-215	131.44±35.97(198)	132.67±36.82(141)	128.41±33.92(57)	-0.35	0.720
Calcium (mg/dl)	7,6-10,4	9.46±0.46 (129)	9.40±0.42 (93)	9.60±0.51(36)	-2.63	0.008*
Magnesium (mg/dl)	1,0-2,8	1.99±0.19 (138)	1.97±0.20 (96)	2.04±0.17(42)	-2.11	0.034*
Sodium (mmol/L)	133-143	139.14±1.98(116)	139.00±1.97(83)	139.48±1.98(33)	-1.46	0.142
TSH (mIU/L)	0.3-5.1	1.79±0.96(140)	1.81±0.98(98)	1.73±0.94(42)	-0.42	0.672
BMI	16-40.4	25.84±4.40(158)	25.45±4.49(109)	26.71±4.10(49)	-2.05	0.040*

*SD: Standard Deviation; BMI: Body Mass Index; *Mann-Whitney U test is significant at 0.05 level (2-tailed); Min: minimum value; Max: maximum value*

When age groups were compared, serum glucose, total cholesterol, triglyceride, LDL-C, sodium levels, and BMI scores were statistically lower in young individuals below 41 years of age versus the elderly group over 42 years old. There was no difference between age groups regarding vitamin D, HDL-C, calcium, magnesium, and TSH levels (Table 3).

Table 2: Correlation of vitamin D3 with biochemical and other parameters

Vitamin D	Total	Women	Men
	r_s value; p-value (n)		
Age (years)	0.103; 0.148 (198)	0.058; 0.493 (141)	0.036; 0.790 (57)

A statistically significant correlation was found between vitamin D and total cholesterol and LDL-C in the young age group. However, serum vitamin D had no significant correlation with serum glucose, triglyceride, HDL-C, calcium, magnesium, sodium, TSH levels, and BMI scores (Table 4).

A linear regression analysis was performed to determine the vitamin D level affecting LDL-C levels in the younger age group below 41 years old. Variables correlated with LDL-C, including vitamin D, age, glucose, triglycerides, and sex, were added to the model for analysis (Table 5).

According to the regression analysis results, in model one, (R = 0.218, R2 = 0.048, F (1, 90) = 4.91, P = 0.037) and in model two, (R = 0.566, R2 = 0.321, F (4, 86) = 8.652, P < 0.001) were found to be significant. Also, in the regression analysis, the decrease in vitamin D level is associated with 0.048% of the increase in LDL-C. However, when other parameters were included in the analyses, the association of vitamin D level with LDL-C level did not reach statistical significance (P=0.309) (Table 6).

DISCUSSION

In our study, serum vitamin D, calcium, and magnesium levels were lower in women than in men, whereas HDL-C was higher in women. In addition, serum glucose, total cholesterol, triglyceride, LDL-C and sodium levels, and BMI scores were lower in young individuals than in the elderly. These findings show that the population evaluated within the scope of our study conforms to normal distribution. In addition, lower serum glucose, triglyceride levels, and BMI scores found in women could be explained by the lower mean age of women.

Findings of no correlation between serum vitamin D with total cholesterol, triglyceride, HDL-C, LDL-C, glucose, calcium, magnesium, sodium, and TSH levels and BMI scores in either men or women in our study contradicts the common view in the literature. In a meta-analysis, it has been reported that vitamin D supplementation decreases total serum cholesterol, triglyceride, and LDL-C levels in patients with type 2 diabetes [15]. Supporting this, in one study conducted on patients with type 2 diabetes, vitamin D supplementation was suggested to reduce serum glucose and triglyceride levels [17]; in another study, higher serum triglyceride levels were associated with lower serum vitamin D levels [18].

Contrary to the findings about vitamin D levels and lower LDL associations, a meta-analysis study found that vitamin D supplementation increased serum LDL-C levels but did not affect HDL-C and triglyceride levels [16]. In a study conducted in the general population in Spain, a statistically significant association was found between total cholesterol and LDL-C levels with vitamin D levels [19]. In another study in Turkey partially similar to our findings, no statistically significant difference was found between total cholesterol, LDL-C, and triglyceride levels compared to vitamin D levels. [20]. Although a negative correlation was found between serum vitamin D and total cholesterol and LDL-C levels in young people in our study, this correlation did not reach significance when other parameters were included.

However, a human epidermal keratocyte cell culture study suggests an indirect effect of vitamin D on cholesterol synthesis, in which total cholesterol synthesis and LDL-C organization were increased in cells exposed to low calcium concentrations [21]. Our study did not support this, and there was no correlation between vitamin D and calcium levels.

The correlation between vitamin D and LDL-C in young people did not persist in the multiple linear regression analysis. In a large-scale study on 11734 individuals from the adult population, LDL-C and calcium levels were significantly higher in the group with high vitamin D levels, and patients with co-morbid situations, type 2 diabetes, hypertension, dyslipidemia, and atherosclerotic heart disease were unlikely to have less Vitamin D deficiency (<20 ng/mL) [22]. However, these studies contradict the widespread belief that vitamin D affects LDL-C and calcium levels.

CONCLUSIONS

As a result, our findings indicate no significant effect of vitamin D on calcium metabolism, and contradictory findings regarding its effects on glucose and lipid parameters suggest that the common view asserting a relationship between vitamin D and several metabolic and hormonal disorders may be inaccurate. Studies suggesting an association between vitamin D and some diseases were usually conducted on limited relevant patient groups. Thus, the margin of error is expected to be high in generalizing the results from limited studies.

For this reason, with the findings of this study and the current literature, it would be necessary to further elaborate on the cause-effect relationships and to conduct new studies.

Conflicts of interest and sources of funding
The authors declare no conflict of interest. The funders had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript; or in the decision to publish the results. This research received no external funding.

Authors' contribution
All authors made substantial contributions to the conception or design of the work or the acquisition, analysis, or interpretation of data for the work.

Ethics approval and consent to participate
Ethical approval was obtained from the İstanbul Training Research Hospital Clinical Research Ethics Committee (Decision no. 09.08.2019, 1944).

Patient consent for publication
Because is a retrospective study, patient consent was not obtained.

Abstract: *Urinary lithiasis is a common pathology in the modern era. Its significance lies in the possible complications that may arise as well as in its potential for recurrence. The treatment and prevention of recurrences of urinary lithiasis often require the intervention of several specialists: urologists, nephrologists, endocrinologists, nutritionists, biochemists, etc. In the last 20 years, the treatment strategy for urinary lithiasis has changed, with minimally invasive methods replacing laparoscopic or open surgery. These are effective and have rare complications. Whichever treatment method is chosen, it may be necessary to temporarily divert the upper urinary tract by inserting double J catheters for preventive, curative, or palliative purposes. Ureteral catheters have had to be improved over time to avoid two major incidents: their migration and colonization. Various materials were used, varying the shape, size, length, guide as well as approaches. The urinary infection-urolithiasis association is frequent, without always being able to specify the cause-effect relationship. The rate of urinary colonization appears to be influenced by the presence of stent colonization as well as the time since the implant. The association of chronic diseases or emergency insertion is associated with an increased risk of urinary colonization. Complications induced by the time of the double J catheter being implanted are rare, and minor and disappear with its removal. In the case of failure to insert a double J ureteral catheter, the alternative would be to perform an ultrasound-guided percutaneous nephrostomy. Double J ureteral catheter insertion is an effective minimally invasive option in the treatment of obstructive urolithiasis.*

Keywords: *urolithiasis, double J catheter, obstructive urolithiasis, urinary colonization*

INTRODUCTION

Urinary lithiasis is a frequent and often recurring pathology, with a changing evolution (asymptomatic or with a noisy clinical picture). Its incidence is increasing in developed countries where the prevalence in the general population varies between 8 and 10%, tripling in the last 40 years.

By the end of the 19th century, phosphate-uric urinary lithiasis with bladder localization prevailed, and starting from the 20th century the oxalic-calcium urinary lithiasis predominates (70-80% of cases) with renal localization. It mainly affects the population between 20 and 60 years old, with a double rate for men compared to those women.

The recurrence rate in this population is approximately 50% between 5 and 10 years, with approximately 10% of patients presenting multiple episodes of lithiasis recurrence [1,2].

Urinary lithiasis is often revealed by nephrotic colic. Acute nephrotic colic represents about 1-2% of examinations in Emergency Departments, and about 6% of them require hospitalization due to their complications [2,3].

The treatment of a simple, uncomplicated nephrotic colic consists of analgesic treatment (NSAIDs in the absence of contraindications), while a complicated nephrotic colic requires hospitalization and often emergency urinary drainage. The technique is usually chosen according to the size, location, and chemical composition of the stones as well as the morphology of the excretory urinary tract.

Prophylaxis of urolithiasis recurrences requires a general metabolic examination as well as a morpho-constitutional and IR spectrophotometric examination of removed stones.

Urological treatments available today are extracorporeal lithotripsy, rigid or flexible ureteroscopy, and percutaneous nephrolithotomy. They use different energies to destroy the calculus: shock waves, pneumatic ballistic energy, Holmium laser, and ultrasounds. The results of these treatments can sometimes be improved by expulsive medical therapy and post-urotherapy.

The new technological discoveries, their effectiveness, as well as the few complications of urological instrumental treatments in urinary lithiasis have led to a decrease in the indications for surgery (laparoscopic or open). They remain used in case of failure of instrumental treatments or cases of giant stones. Thus, in less than 20 years, the urolithiasis treatment strategy has changed through the use of mini-invasive and highly effective methods [4].

The indications for instrumental urological treatment of urinary stones are:
- symptomatic stones: pain, hematuria, infection;
- complicated stones: urinary obstruction, infection;
- evolutionary stones: the increase of calculus size measured by imaging means;
- stones of significant size: over 1.5 cm for kidney stones and over 6 mm for ureteral stones;
- evolutionary lithiasis disease: the presence of more than two episodes per year;
- infected or infectious stones;
- at the request of the patient;
- in fragile or complex patients (single kidney, kidney failure, heart failure, anticoagulated, etc).

DOUBLE J URETERAL CATHETERS

Regardless of the treatment method approach for urinary lithiasis, it may be necessary to insert a double J endo-prosthesis or catheter for a defined period in case of complete obstruction or secondary infection [5].

Today, the use of double J ureteral catheters is common practice in urology departments.

According to medical dictionaries, a stent is defined either as a device used to maintain an opening, cavity, or contour or as a catheter with a tubular structure intended to maintain an open lumen. The word stent became common in the specialized literature when Montie explicitly defined it as "an intraluminal device to maintain patency of the ureter until healing occurs" [6].

The concept of ureteral stent appears as an adjunct to open surgery to achieve drainage of the upper urinary tract ensuring the continuity of the ureters. In the 19th century, Gustav Simon places a tube in the ureters during a cystostomy and in 1839 Joaquin Albarrano creates the first ureteral catheter made of varnished textile material. In 1952, Tulluch described the use of polyethylene tubes to "repair" ureters and fistulas, and in 1967 Zimskind endoscopically inserted the first silicone ureteral catheter. Their main defect seems to be the migration of the catheters in both directions, and to eliminate it, in 1978 Finney describes for the first time the double J ureteral catheter, provided with loops at both ends [6].

The JJ ureteral catheter used today is an auto-static, flexible tube made of polyurethane or silicone, with curved ends to be able to maintain it between the kidney at the upper extremity and urinary bladder at the lower extremity [7,8,9].

Double J ureteral catheters must comply with the following conditions:
- to be radio-opaque for good visibility on radiography;
- to be provided with visible marks during endoscopy for good positioning;
- have a low surface tension to limit friction during insertion;
- to be inserted anterograde or retrograde;
- to be simple to insert, change, extract, biocompatible and resistant;
- to have a good caliber for urine drainage and at the same time a low risk of obstruction;
- have a low price.

Regardless of the purpose of its insertion (preventive, curative, palliative) or its indications, the double J catheter must ensure the derivation of the upper urinary system by physiological pathways and the flow of urine from the kidney to the bladder [10,11]. It suppresses the pressure due to the lithic obstruction eliminating the pain and by increasing the caliber of the ureter facilitates the migration of stones or their extraction by ureteroscopy.

The indications of the double J catheter are:
- ureteral obstruction by calculus responsible for nephrotic colic;
- preventively, before extra-corporeal lithotripsy to avoid possible obstruction with residual fragment;
- in the case of complicated pelvic surgeries (urological, digestive, gynecological);
- in the case of extrinsic compression of the ureter (tumors, fibrosis, etc.);
- in congenital anomalies, trauma, or iatrogenic insults.

Over time, methods have been sought to decrease the colonization rate of ureteral catheters by using different materials (silicone, polyethylene, polyurethane, biodegradable materials) or by covering the catheters with thin protective films (heparin, silver, polytetrafluoroethylene, antibiotics) [12]. Some urease inhibitors have been used to reduce and prevent stent encrustation or obstruction [13].

In the case of urolithiasis with complete obstruction, there is an indication for the derivation of the upper urinary system by inserting double J catheters, and in case of failure, a percutaneous nephrostomy guided by ultrasound will be performed [14]. This more aggressive technique aims to obtain a kidney without residual fragments at the end of the intervention.

The catheters vary in size (from 3 to 9), length (between 12 and 30 cm), guide (simple metal, Teflon, lubricated polyurethane monofilament), material (polyvinyl chloride, silicone) [15,16, 17].

The catheter is inserted under general anesthesia or loco-regional anesthesia [18].

Two approaches can be used [19]:
- naturally through cystoscopy under radiological control;
- percutaneously after renal puncture (nephrostomy) under radiological control.

The J catheter can be kept from a few days to a few months (generally 3 months) depending on the indications. Removing too early can be ineffective and complications (calcifications, obstructions) can occur if kept too long [20].

During catheter indwelling, various unwanted effects can be mentioned [21,22,23]:
- frequent urination (indication of anticholinergics);
- lumbar pain during urination (indication of minor analgesics);
- bladder discomfort (indication of antispasmodics);
- hematuria (indication of correct hydration – 1.5 l/24 h and avoidance of physical efforts);
- urinary infections (indication for antibiotic treatment).

The ablation of the JJ catheter is generally done by cystoscopy, under local anesthesia, or in ambulatory care (takes less than 5 min).

COMPLICATIONS

There is a frequent association between urinary infection and urolithiasis. However, it is difficult to determine if the calculus became infected secondarily or if the infection preceded the calculus and was responsible for its formation.

According to European and American scientific societies, urinary infections are defined by the association of significant bacteriuria with symptoms evocative of a urinary infection in the absence of another infectious focus. Symptoms and clinical signs compatible with a urinary infection can be varied, from functional urinary signs such as pollakiuria, and burning during urination – to non-specific symptoms such as fever, chills, psychomotor retardation, confusion, spasticity, etc. Urinary colonization corresponds to the presence of one or more microorganisms in the urinary tree without generating clinical manifestations. A urinary infection is considered if the clinical signs and symptoms are associated with a bacteriuria higher than 105 CFU/ml (103 CFU/ml for women and 104 CFU/ml for children). It is known that immunosuppressed, pregnant women, alcoholics, and malnourished, patients with chronic renal or neurological diseases have a higher rate of urinary colonization.

The risk of urinary colonization is significantly higher in patients with colonized JJ catheters, especially if the indwelling time is over 45 days.

Complications related to the maintenance of the double-J catheter are rare (hematuria, infection and/or colonization, catheter fragmentation, encrustation) and occur especially with long-term stent indwelling (more than 30 days) and disappear with its ablation.

Failing to remove all residual fragments after instrumental urological treatment of urolithiasis is a major factor of recurrence (50%), even for residual fragments smaller than 2 mm. Under these conditions, any instrumental treatment must be systematically imaging evaluated every 3 months with a reno-vesical CT or ASP + reno-vesical ultrasound.

In the case of residual fragments after a urological instrumental treatment, there are two possibilities:

- expulsive medical treatment: the administration of an alpha-blocker (tamsulosin) would favor the elimination of the fragments and reduce the painful crises associated with their elimination;

- post-urotherapy performed in ventral decubitus and incline at 30o - 45o to favor the elimination of sedimented fragments in the lower calyces.

Any urinary calculus requires a complex examination consisting of a morpho-constitutional analysis and IR spectrophotometry, metabolic balance, dietary survey, hygienic-dietary measures, and possibly medical treatment.

CONCLUSIONS

The treatment strategy for obstructive urolithiasis has changed in the last 20 years with the new high-performance, mini-invasive techniques.

Double J ureteral catheter insertion in obstructive urolithiasis is a minimally invasive option for high urinary tract diversion, regardless of the treatment method chosen for urolithiasis.

The double J catheter can be inserted for different purposes: preventive, curative, and palliative.

The risk of urinary colonization is significantly higher in patients with colonized JJ ureteral stents.

The prevalence of urinary colonization increases with the indwelling time, especially in the case of emergency insertion.

The association of chronic diseases such as diabetes, hypertension, CKD, and disabling neurological diseases is associated with an increased risk of urinary colonization.

In pelvic ureteral lithiasis, spontaneous expulsion of the stone is possible, probably due to ureteral dilatation secondary to the presence of the ureteral prosthesis.

Complications related to the indwelling of the double J catheter are rare and occur especially in the case of long-term indwelling (more than 30 days) and disappear with its ablation.

In case of failure to insert a double J ureteral catheter, the alternative for a high urinary system derivation is an ultrasound-guided percutaneous nephrostomy.

ADMINISTRATIVE ISSUES

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers may cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor may not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Editor-in-Chief. The Editor-in-Chief reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at: http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

– Accessible to the public at no charge;

– Searchable by standard, electronic (Internet-based) methods;

– Open to all prospective registrants free of charge or at minimal cost;

– Validates registered information;

– Identifies trials with a unique number; and

– Includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, a target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The Journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 200 words. Abstracts for original articles should be formatted as detailed in the word form. Titles must not be longer than 120 characters (including spaces). In every article, there must be three to ten pertinent keywords specific to the article yet reasonably common within the subject discipline.

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article. This should be cited as Rom. J. Mil. Med. (year); (vol): [issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related “miniseries” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this

avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are suggested to limit to 3000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Executive Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as ‘What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?’ Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate.

Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised ‘Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication, as presented at http://www.ICMJE.org/.

Spelling

The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units

All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations

Abbreviations should be used sparingly and only where they ease the reader's task by reducing the repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: the title page; the main text file according to the word model.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or an article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented according to the word model. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 200 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. If appropriate, divide the abstract with the headings: Background and Aim, Methods, Results, and Conclusions. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to ten keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser – http://www.nlm.nih.gov/mesh/meshhhome.html.

Text

Authors should use the word form in editing the submitted material.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square parentheses in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or fewer; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

Use Index Medicus as the style guide for references and other journal abbreviations.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table and legend must be

understandable without reference to the text. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, •, ▸ should be used (in that order) and *, **, *** should be reserved for P-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication:

Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com. A cover letter containing an authorship statement should be included. The cover letter should include a statement covering each of the following areas:

– Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author. It is not accepted the idea of equal contribution.

– Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.

– A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

– For research involving pharmacological agents, devices, or medical technology, a clear Conflict of Interest statement about any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

– For clinical trials, these have been registered in a publically accessible database (see more under ‘ETHICAL CONSIDERATIONS (Further Information)’ later in these guidelines).

If the above items are not included in the cover letter, manuscripts cannot be sent for review. Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section ‘Parts of the manuscript’, including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using the word model that is to be found on the web page (http://revistamedicinamilitara.ro/wpcontent/uploads/2022/07/Macheta-articole.docx).

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, high-resolution figures (at least 300 d.p.i.) saved as .eps, .jpg or .tif files are required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted Articles

Accepted Articles are published online after final acceptance, and appear in PDF format only.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing the proof of acceptance. It is therefore essential that a working e-mail address is provided for the corresponding author.

COPYRIGHT, LICENSING, AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is submitted.

ORIGINAL ARTICLE

Laparoscopic Wedge Resection for Gastric Mesenchymal Tumor – Small Case Series

Doru Moga[1], Adrian Popențiu[1], Daniel Popa[2]

[1] Department of Surgery, Military Emergency Hospital Sibiu and Lucian Blaga University Sibiu, Romania
[2] Department of Gastroenterology, Military Emergency Hospital Sibiu and Lucian Blaga University Sibiu, Romania

Correspondence: Doru Moga, mogadoru@yahoo.com

Abstract: *Introduction: Gastric mesenchymal tumors are a pathology that is increasing in incidence in recent years but the treatment is not yet standardized. The laparoscopic approach to these lesions is a modern option, with the patient benefiting from the advantages of minimally invasive surgery. Methods: We included in the study 4 patients operated laparoscopically for suspicion of gastric GISTs between Mars 2019 and May 2022. From a prospectively kept database, we extracted the following characteristics: age, sex, length of postoperative hospital admission, operation time, tumor location, tumor size, histopathological assessment of resection margins, intraoperative blood loss, and incidence of postoperative complications. Results: Average tumor size was 4.3 cm, ranging from 4 to 6 cm. Laparoscopic wedge resection was possible in all cases. There was no conversion, no episode of tumor rupture or spillage, and no major intraoperative complications. Histology confirmed a GIST in 3 of 4 cases. In one case histological workup showed gastric schwannoma. Conclusion: Laparoscopic wedge resection for gastric stromal tumors, even larger than 5 cm, appears to be safe and feasible in selected patients, with acceptable operative time and oncological outcome after an intermediate follow-up. More important than the size of tumors that are approached laparoscopically is their location and the possibility of a stenosis-free resection.*

Keywords: *laparoscopic wedge resection, Gastrointestinal Stromal Tumors (GIST), gastric mesenchymal tumors, Schwannoma*

INTRODUCTION

Gastric tumors can be divided into epithelial and subepithelial tumors based on their origin. 90% of gastric tumors including adenoma and adenocarcinoma originate from epithelium [1]. Various tumors occur as subepithelial lesions, including mainly gastrointestinal stromal tumors (GISTs) and leiomyomas, less often neuroendocrine tumors, schwannoma, lymphangioma [1], lipomas, granular cell tumors, and ectopic pancreatic tissue [2].

Epidemiology

GIST is the most common mesenchymal tumor of the gastrointestinal tract [3], with an incidence of about 1-1.5/100,000 persons/year [4,5]. Few studies have indicated that the incidence of GIST is greater in patients undergoing bariatric surgery (0.6%- 0.8%) than in the general population [6]. Increased body mass index has been linked with a higher risk for several types of cancer. Another possible hypothesis for the high incidence found in these studies is that many small, asymptomatic GISTs are underdiagnosed in the general population [7,8].

Gastric stromal tumors account for about 60-70% of all GISTs [4,9,10]. The term is relatively recent, it was first used in 1983, to reclassify a subset of tumors previously identified as leiomyomas or leiomyosarcomas [11,12]. Typically, GISTs are solitary tumors identified slightly more often in males than females of middle to advanced age (between 40 and 80 years) [6,7]; however, the estimated mean age at diagnosis is in the sixth decade of life [13].

Histological Findings

GIST originates from the interstitial cells of Cajal, the pacemakers of the gastrointestinal tract [14], or their stem cell precursors [15]. Their defining characteristic is a gain-of-function mutation in genes coding for the KIT tyrosine kinase receptor, which is considered the driving force of cell proliferation in this tumor [16].

Diagnosis of GIST was based on microscopic analysis, including immunohistochemistry with a panel of antibodies: Cluster of

Differentiation-117 (CD117), Cluster of Differentiation-34 (CD34) and Discovered on GIST-1 (DOG1), S-100 protein, desmin, and smooth muscle actin [17,18].

Natural Evolution

GISTs are not classified as either benign or malignant but are rather stratified by their clinical risk of malignancy: very low, low, intermediate, or high [13]. The malignant potential depends on tumor cell mitosis, tumor size, tumor location [17, 19], and tumor rupture [5]. Approximately 10% to 30% of GISTs have a malignant clinical course [13] because they can metastasize hematogenously to the solid viscera, including the liver, small bowel, and lungs [14]. In these conditions, the only absolute signs of malignancy are metastasis or invasion into adjacent organs [16].

Biologically, tumors grow locally within the stomach wall (intra- or extraluminal expansion) and can also spread along the smooth muscle planes within the stomach or can rupture into the peritoneal cavity causing sarcomatosis [10].

Clinical presentation and incidental GIST

The most common symptoms of GISTs are gastrointestinal bleeding, including acute melena and hematemesis [13] with subsequent anemia, weakness, and abdominal pain [18], distension, and discomfort due to a tumor-induced mass effect or metastasizing tumors [16]. Tumor hemorrhage commonly occurs when large tumors develop an ischemic, punctate ulcer. Usually, the bleeding can be controlled using endoscopic sclerotherapy or electrosurgical coagulation techniques [10].

15% to 30% of patients with GISTs are asymptomatic and are diagnosed incidentally, during examinations for other reasons, during surgery for other diseases [6,15], or during postmortem autopsy [13]. In these asymptomatic patients, tumors grow insidiously and can sometimes reach large sizes.

Diagnostic Process

With the popularity of screening endoscopy, increasing gastric submucosal tumors are incidentally detected [20]. The main endoscopic finding of GISTs is common to all subepithelial lesions: a nonspecific smooth bulge covered with normal mucosa [13].

Diagnostic workup can be challenging and consists of endoscopy, ultrasonography, computed tomography, magnetic resonance imaging, and endoscopic ultrasonography with fine needle aspiration [13]. However, a biopsy specimen is often negative [15].

Treatment

The treatment strategy for immunohistologically confirmed GISTs is as follows: surgical resection is the first choice for resectable GISTs without metastasis and administration of imatinib is the primary approach for unresectable, metastatic, or recurrent GISTs [13].

Medical Treatment

In 2000, imatinib (first-line tyrosine kinase inhibitor) was first used to treat patients with advanced GIST, achieving unprecedented treatment responses in a tumor type that – when metastatic – was previously rapidly lethal [12]. The drug was approved for use as adjuvant treatment after the surgical removal of high-risk GISTs in 2012 when it is administered in an attempt to reduce the recurrence rate [8]. Sunitinib (second-line tyrosine kinase inhibitor) and Regorafenib (third-line multikinase inhibitor) can be used in advanced cases after treatment failure with Imatinib. However, it is difficult to obtain a permanent cure with tyrosine kinase inhibitors [13].

Surgical Treatment

In contrast to gastric adenocarcinoma, where gastrectomy with wide margins and lymphadenectomy is recommended [10], limited gastric resection is the recommended surgical approach for GIST, because it grows by expansion rather than diffuse infiltration and rarely invades nearby lymph nodes [5, 14,19]. Wide margins and lymph node dissection do not improve survival or decrease recurrence [11].

The surgery aims to achieve a complete resection with no tumor residue [17,21]. Moreover, strict avoidance of intraoperative tumor rupture is crucial for preventing tumor relapse [16].

Traditionally gastric GISTs resection was done with open surgery, but, more recently, less invasive methods have been reported [18]. The first description of laparoscopic resection of a GIST was in 1992 when Lukaszczyk discovered and resected an incidental gastric mass during a laparoscopic cholecystectomy [11]. The choice of the laparoscopic or open method was made by the surgeon based on his evaluation and the patient's consent [19].

As experience accumulated, initially tumors up to 2 cm [18, 22], then between 2 and 5 cm [4], and more recently between 5 and 10 cm were approached laparoscopically [21]. Prerequisites for the laparoscopic approach were the absence of metastases and the presence of a well-defined tumor on CT scanning without the involvement of adjacent organs, the esophagogastric junction, or the pylorus of the stomach [18, 19]. However, wedge resection sometimes involves inadvertent resection of additional gastric tissue, which can produce gastric deformation. Anatomic gastrectomy (subtotal or total gastrectomy) is reserved for large tumors that involve a significant portion of the stomach [10].

METHODS

After obtaining our institutional review board approval, we retrospectively reviewed the medical records of our patients operated laparoscopically for gastric GISTs between March 2019 and May 2022.

Study Population and Data Analysis

We extracted the following characteristics: age, sex, length of postoperative hospital admission duration, operation time, tumor location, tumor size, histopathological assessment of resection margins, intraoperative blood loss, and incidence of postoperative complications (surgical and non-surgical). Patients were eligible for laparoscopic surgery if preoperative staging (endoscopy and CT scan) showed a localized, non-metastatic extra mucosal gastric lesion (Figures 1, 2). Tumors were required to be of a diameter and in a position that suggested resectability through segmental or wedge resection. Preoperative histological confirmation of the diagnosis was not a prerequisite for inclusion.

Figure 1: Subepithelial gastric tumor with a clot on the surface (Case 4)

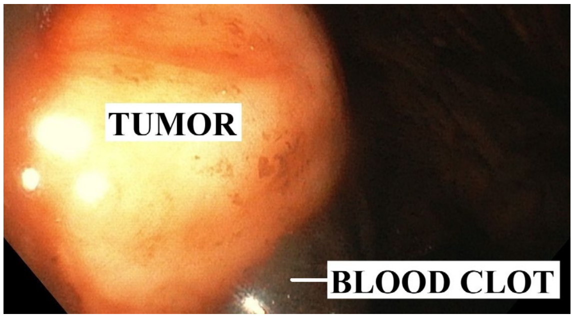

Figure 2: CT scan image (Case 1)

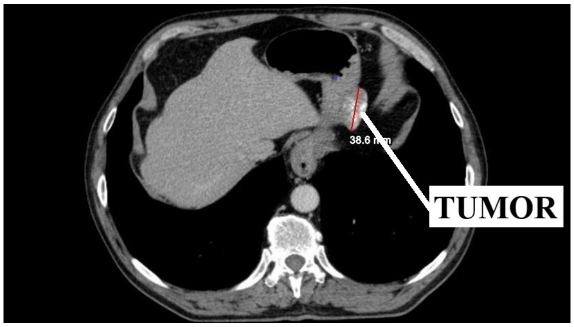
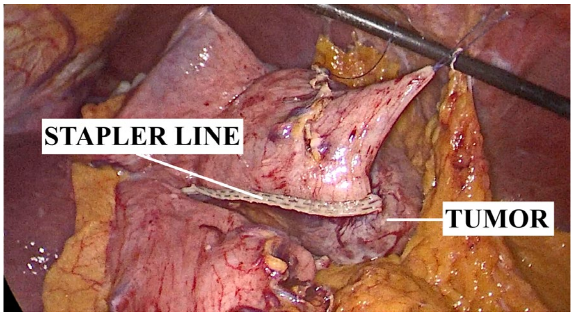


Surgical Resection Procedures

All patients were treated by laparoscopy while under general anesthesia. The patient was placed supine in the anti-Trendelenburg position and the surgeon stood between the legs. Using a Veress needle, the pneumoperitoneum was achieved with CO_2 at 12 mmHg pressure. The first trocar was placed on the median line, about 15 cm from the xiphoid process. Under visual control, another 3 or 4 work trocars were introduced. After checking all the abdominal cavities for metastases, the lesion was identified through visualization and palpation. In the case of tumor location at the posterior wall of the stomach, the gastrocolic ligament was dissected and the stomach was inverted to display the lesion. The tumor-bearing gastric segment was resected with several 60 mm endoscopic linear staplers (EndoGIA) (Figure 3). To avoid stenosis of the stomach during wedge resection, a calibration tube (36 Fr) was inserted by the anesthesiologist. Special care has to be taken to prevent peritoneal seeding and the possibility of capsular rupture during manipulation.

Figure 3: Intraoperative image, after the first EndoGIA cartridge is placed (Case 4)



The resection specimen was placed into a plastic retrieval bag and removed through one of the extended port incisions. Stapler lines were visually controlled and, if deemed necessary by the surgeon, their integrity was assessed through the application of methylene blue solution via a nasogastric tube (blue test). At the end of the operation, a drain tube was placed in the vicinity of the staple line.

Pathological evaluation

The specimens were fixed in 10% formalin solution and sent for pathological evaluation. The characteristics of gross specimens were described, including tumor size, gross appearance, ulceration (Figures 4, 5). After sectioning, hematoxylin and eosin staining was regularly performed followed by immunohistochemical staining.

Figure 4: The specimen, after extraction (Case 3)

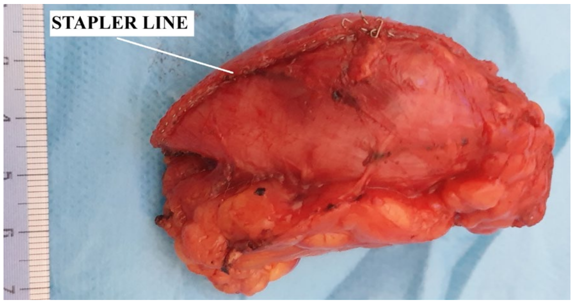


Figure 5: The specimen, with the suture line open (for inspection of the resection margins) (Case 2)

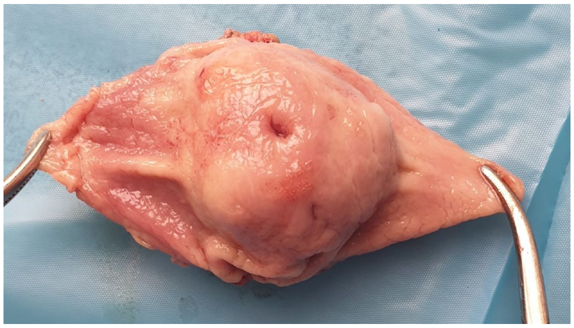

Follow up

Patients with immunohistochemically confirmed GIST were referred to the oncology department for therapeutic management

RESULTS

Four patients were planned for a laparoscopic wedge resection of a suspected gastric GIST. The presented cases were 3 females and 1 male with a median age of 70.25 years (between 64 and 74 years).

The reasons for admission to Gastroenterology Department were abdominal pain (3 patients), weakness (2 patients), anemia (2 patients), and gastrointestinal bleeding (1 patient).

All patients were investigated by endoscopy and CT scan. The average tumor size was 4.3 cm, ranging from 4 to 6 cm. The main patient data are summarized in Table 1.

The average operation time was 77.5 min, ranging from 60 to 100 min. Resection was performed using between 2 and 3 cartridges. Because the operated lesions were large, there was no need for intraoperative endoscopy to identify the tumor's location. Laparoscopic wedge resection was possible in all cases. There was no conversion, no episode of tumor rupture or spillage, and no major intraoperative complications. Intraoperative blood loss was below 50 mL in all patients and no patient required blood transfusions. The surgical margin of all tumors was confirmed using the extracted specimen.

All tumors were resected with macroscopic and pathologically negative margins. Histology confirmed a GIST in 3 of 4 cases. In one case histological workup showed gastric schwannoma.

The median postoperative hospital stay was 5.5 days, ranging from 5 to 7 days. Hospitalization was 5 days for 3 of the patients and 7 days for one patient who had a postoperative complication. One patient (with a tumor size of 3.5 cm) experienced a postoperative hemorrhage (grade II complication after Clavien-Dindo classification). This was treated conservatively with proton pump inhibitors. We had not identified any other postoperative complication.

Table 1: Patients data

Case number	1	2	3	4
Age	74	71	64	72
Sex	Male	Female	Female	Female
Histology	GIST	GIST	Schwannoma	GIST
Location	Fundus/ Greater curvature/ Anterior wall	Body of the stomach/ Lesser curvature/ Posterior wall	Body of the stomach/ Lesser curvature/ Anterior wall	Body of the stomach/ Greater curvature/ Posterior wall
Morphology	Pediculated	Extraluminal	Extraluminal	Extraluminal
Operation time	70 minutes	100 minutes	80 minutes	60 minutes
Number of cartridges	2	2	2	3
Dimension of resection	6x5 cm	7x6 cm	6.2x5 cm	9x8 cm
Tumor size	4 cm	3.5 cm	4 cm	6 cm
Tumor staging	pT_2	pT_2	-	pT_3
Risk of malignancy	Very low	Low	-	High

In the same period, outside this study, in our department, a patient with a massive tumor (18.8/18/13 cm) was treated by open subtotal gastrectomy.

All patients were referred for oncological consultation, but only 2 patients did it. Due to the favorable histopathological exam, absence of distant metastases at the time of diagnosis and on the subsequent follow-up (annually CT), and absence of local recurrence on follow-up endoscopy (6 months postoperatively, then annually), the patients did not indicate adjuvant chemotherapy.

All patients were alive at the end of this study and in good health.

DISCUSSION

Open surgery was the traditional and most widely used treatment for gastric stromal tumors. When possible, the endoscopic or laparoscopic approach is safe and leads to non-inferior outcomes compared to the open approach [21].

Although our experience is limited, we can state that the cases we have treated by laparoscopic wedge resection and presented have progressed favorably, benefiting from the well-known advantages of laparoscopic surgery. Among the other variants of the laparoscopic approach found in the literature, we list the following: non-anatomic full-thickness removal of a disk of tissue with the closure of the resulting gastrotomy, anatomic partial gastrectomy with reconstruction, and transgastric resection [11].

The choice of laparoscopic approach must take into account both the size of the tumor and its location. Visible lesions on the anterior gastric wall are most suitable for wedge resection, consisting of lifting the lesion and performing a wedge resection by application of one or more endoscopic linear stapler devices. But selected cases can be approached laparoscopically even if they are not located on the anterior wall. On the other hand, patients with lesions near cardia or pyloric antrum are not proper candidates for wedge resection due to potential stenosis. Therefore, limited gastrectomy is usually used, but alterations of anatomic structures may lead to functional disturbance and impaired quality of life [20]. In our patients, we did not find any early postoperative stenosis. Concerning long-term functional results, we were not confronted with symptoms or endoscopic signs of reflux or stenosis during postoperative follow-up.

As experience with minimally invasive surgery has increased over the past decade, laparoscopic surgery for gastrointestinal malignancies has become increasingly common [5]. As in other laparoscopic procedures, the existence of a learning curve must be assumed. However, due to the experience gained by the two senior surgeon authors in oncological surgery and bariatric surgery (sleeve gastrectomy), the surgical interventions for the presented cases were carried out in good conditions. Being tumors with malignant potential, all measures must be taken to prevent tumor injury.

In our small case series, 1 out of 4 tumors preoperatively suspected to be a GIST were histologically diagnosed as gastric schwannoma. Schwannomas are benign, slow-growing, encapsulated nerve-sheath tumors arising from Schwann cells, meant for the myelin sheath formation in the peripheral nervous system. Gastric schwannoma is a rare gastric mesenchymal tumor, which accounts for 6.3% of the gastric mesenchymal tumor, 4% of all benign gastric tumors, and 0.2% of all gastric tumors. Being different from GISTs, they are considered as being benign, slowly growing, and with excellent prognosis [20]. Retrospectively, in this case, surgical resection would have not been required for oncological reasons. We also found this situation in the literature studied [14,16,23], and it's explainable because we didn't have a preoperative histological diagnosis. On the other hand, it is considered that all localized resectable gastric stromal tumors with a diameter of 2 cm or more need resection [2,4]. Preoperative histological diagnosis of submucosal gastric lesions is however not always feasible through endoscopic biopsy [16]. With the benign and mostly asymptomatic nature of gastric schwannomas, endoscopic follow-up is also an alternative method. But it is not widely adopted due to the lack of a standardized surveillance strategy, the risk and cost-effectiveness of repeated endoscopic procedures, and patients’ stress and compliance [20].

CONCLUSIONS

In conclusion, laparoscopic wedge resection for gastric GIST, even larger than 5 cm, appears to be safe and feasible in selected patients, with acceptable operative time and oncological outcome after an intermediate follow-up.

More important than the size of tumors that are approached laparoscopically is their location and the possibility of a stenosis-free resection.

Abstract: *Psoriasis is a chronic inflammatory skin condition with genetic determinism characterized by the presence of well-defined, erythematous plaques, covered by white, pearly, stratified scales, located on the extension areas, the skin of the scalp, intertriginous regions. The origin of psoriasis is multifactorial, involving hereditary and environmental pathogenic mechanisms. It is triggered by various risk factors involving a variety of processes, such as inflammation, antigen presentation, cell signaling, and transcriptional regulation.*

Keywords: *psoriasis vulgaris, inflammation, immune system*

OVERVIEW

Definition

To have a starting point and be able to go deeper into a subject, as in any field, and in the case of diseases, we must first know the definition. A definition must be as complete as possible, to create an overall picture of the disease.

Psoriasis is a chronic inflammatory skin condition [1], proliferative [2], with genetic determinism [3], characterized from a clinical point of view by the presence of well-defined, erythematous plaques [4], covered by white, pearly, stratified scales [5], located on the extension areas and in the skin of the scalp.

If it was initially considered a benign dermatological condition, psoriasis is now accompanied by multiple comorbidities, being considered a multisystemic inflammatory disease [6]. In addition to the impact it has from an aesthetic point of view, psoriasis also significantly influences patients' quality of life [7].

A recent study estimated that the psychological impact in patients with psoriasis is severe, between 10-62% [8]. Among the most common symptoms are: low self-esteem, sexual dysfunction, suicidal ideation, which occurs in up to 10% of patients with psoriasis, decreased professional opportunities, stress – which can trigger psoriasis flare-ups, depression [8].

Incidence

Worldwide, the prevalence of psoriasis is between 0.5%-11.4% in adults [9], and this increases with increasing distance from the Equator [10]. Recent studies have shown that in Australia the prevalence of psoriasis in adults is between 2.3% - 6.6% and 1.3% - 2.2% in the United Kingdom [11].

While most cases of psoriasis often appear before age 35, it can develop at any age [12], and men and women are equally affected [13].

ETIOPATHOGENESIS

The cause of psoriasis is not known, but it was found to be a condition with multifactorial determinism [14], which to manifest itself clinically requires the presence of genetic and environmental factors [12].

About 40% of people with psoriasis or psoriatic arthritis have a family member with psoriasis [15].

The major susceptibility locus in psoriasis: PSORS 1 (6p21.3) within the MHC gene complex is present in approximately 30% of patients with psoriasis [15].

In patients with genetic predisposition, environmental factors can have a triggering or aggravating effect on the disease, and among the most frequently involved environmental factors are: trauma, infections, endocrine factors, certain drugs, alcohol, smoking, and obesity [16].

Pathogenic hypotheses

As mentioned, the origin of psoriasis is multifactorial, involving hereditary and environmental pathogenic mechanisms [17]. At the epidermal level, there is hyperproliferation and abnormal differentiation of keratinocytes, as well as activation of the skin's immune system [18].

Human histocompatibility system (HLA)

The major histocompatibility complex (MHC) also known as human leukocyte antigen (HLA) is one of the most genetically diverse regions in the genomes of different species [18].

More than 500 associations have been identified in the HLA region for approximately 200 phenotypes, including immune deficiencies, autoimmune diseases, susceptibility to infections, malignancies, and psychiatric conditions (Welter et al. 2014) [18].

The function of gene families at the level of MHC in the occurrence of autoimmune diseases has been the subject of research for decades [19].

Psoriasis is characterized by epidermal hyperproliferation and dermal inflammation [20], mediated by T cells [21]. Efforts to study genetics in psoriasis continue, with nine susceptibility loci (PSORS1-9) being identified [22]. The PSORS1 locus is considered the genetic determinant of psoriasis [23].

From the human genome, MHC is one of the most studied regions [24], with multiple genetic variants at this level that have contributed to the emergence of diseases such as psoriasis, Crohn's disease, systemic lupus erythematosus, rheumatoid arthritis [25].

MHC is located on chromosome 6p21.3 and is divided into 3 regions: the centromeric region (MHC III) and the telomeric regions (MHC I and II) [26].

The genome-wide association study (GWAS) demonstrated that at the MHC level there are SNPs associated with the occurrence of psoriasis [27].

The major locus involved in the development of psoriasis – PSORS 1 – located at the MHC level is probably associated with non-MHC loci with common alleles [28], which determines the genetic heterogeneity of psoriasis [29].

Certain gene combinations increase the risk of psoriasis, while others decrease it. Patients with psoriasis have been observed to have a higher prevalence of HLA-Cw6, HLA-B13, HLA-Bw17, and HLA-B37 antigens [27].

Major susceptibility locus (PSORS1)

While the major susceptibility locus is PSORS1, other susceptibility loci seem to also play important roles: PSORS2 (17q24-q25) [26].

Molecular studies revealed the following "candidate" genes for psoriasis:
- Gene S located on HLA-Cw6 (expresses the duration of keratinocyte differentiation) [26].
- Genes from the differentiation complex PSORS4 (1q21-q22) - encoding molecules involved in the terminal differentiation of keratinocytes [28].
- PSORS 5 (predisposition in Swedish families) [26].
- PSORS 8 (susceptibility to Crohn's disease and psoriatic arthritis [27].
- PSORS 9 (predisposition in Chinese families) [28].

The immune system

Psoriasis is an incurable autoimmune disease with genetic determinism, mediated by T lymphocytes…

Immunity includes all the physiological mechanisms that allow the body to recognize and eliminate a "non-self" antigen [30]. To be effective, the immune system must differentiate between "self" – cells, proteins that belong to the body and "non-self" – pathogens or substances foreign to the body [31].

There are two types of immune system response:
- Innate immunity = non-specific (which generates an immediate response)
- Acquired immunity = specific

Innate immunity includes two main lines of defense:
A) Physical barriers: skin, mucous membranes, cilia.
B) Chemical barriers: saliva, mucus, acid environment in the stomach, sweat, lysozyme.

Acquired immunity involves:
- The inflammatory response
- The complement system
- Cellular components

The innate immune response is naturally present in humans and is not pathogen-specific. The acquired immune response triggers a specific cell-mediated response through T lymphocytes, which secrete cytokines, and humoral through B lymphocytes, which secrete antibodies [31].

Psoriasis, the chronic inflammatory skin disease [1], is characterized by abnormal innate and acquired immunity [30], which is associated with aberrant differentiation and hyperproliferation of keratinocytes [31].

Pathogenic hypotheses

Psoriasis is a complex genetic disorder that is triggered by various risk factors involving a variety of processes, such as inflammation, antigen presentation, cell signaling, and transcriptional regulation [33]. Persistent inflammation in psoriasis causes uncontrolled differentiation and proliferation of keratinocytes [34]. It is considered that both keratinocytes and other cell types are involved in the appearance of the psoriatic plaque, from whose interaction in the superficial epidermal layers the persistent inflammation results [35].

From a histological point of view, the changes that appear in psoriasiform skin are acanthosis, parakeratosis, and hyperkeratosis [36].

In the most recent meta-analysis performed on genome-wide association studies, 15 new PSORS-type loci were identified, bringing their number to 36 [37]. Among the loci identified are several that encode the NFkB signal transduction cascade, such as REL, NFKBIA, TRAF6, CARD14, and ILF3 [37].

Studies at the level of the entire genome emphasize the complexity of gene changes involved in the occurrence of psoriasis [38].

In several reports, the role of the nervous system in the pathogenesis of psoriasis was emphasized, and its involvement was based on the symmetrical distribution of lesions on the body and the interaction of sensitive peripheral nerves with immunomodulatory networks [39].

Cases have also been reported in which surgical denervation of psoriasis lesions or local anesthesia would decrease local inflammation [39].

Emotional stress, as well, has been reported as being involved in the onset of psoriasis or its exacerbation [40].

Over time, research has shown that the immune system has a key role in the development of psoriasis [41].

Classically, psoriasis is a systemic inflammatory disease [1], controlled by T cells [3], and modulated by genetic and environmental factors [2].

The presence of macrophages, lymphocytes, and neutrophils in the skin is a characteristic sign of psoriasis [7]. Therefore, the disruption of the innate and adaptive skin immune response, to which is added the presence of non-immune cells, determines the support of inflammation [9].

THE ACTIVE MOLECULAR ENVIRONMENT IN PSORIASIS

The activity of the immune system does not consist only in its specificity, but also in the elaborated communication network through the cytokines secreted by the activated immune cells [42].

Cytokines are small, soluble proteins that allow the recruitment of other immune cells, such as T lymphocytes or dendritic cells, and are involved in identifying the site of infection [43].

The key groups of cytokines are represented by: IL, interferon (IFN), and tumor necrosis factors (TNF) [42].

IL-1 is produced by macrophages, monocytes and other types of cells, being composed of IL-alpha and IL-beta, with a key role in the inflammatory response [44].

It binds to the specific receptor – IL-1R and its accessory protein (IL-1RAcP) [43], further activating a complex intracellular signaling network [45].

This ultimately leads to the induction of transcription factors, such as NFκB, resulting in inflammatory immune responses [46].

The IL-beta subunit has an important role in psoriasis, inducing the proliferation of T cells, which produce IL-17 and thus maintain the inflammatory processes in psoriasis [47].

Therapies targeting IL-1 have not demonstrated satisfactory results in plaque psoriasis, but satisfactory results have been obtained in generalized pustular psoriasis [45].

IL-23 is a cytokine formed by two subunits, p19 and p40 [48], involved in antifungal and antibacterial defense [49]. It is produced by macrophages and dendritic cells, and the receptor to which it binds consists of IL-23 R and IL-12Rbeta1 [50]. Furthermore, it determines the activation of transcription factors, including STAT-3 [51].

It cannot activate naive T cells alone, because they do not have specific receptors, but it is involved in the pathogenesis of psoriasis through Th 17 cells [52].

The development of anti-IL-23 therapies has shown excellent efficacy in the treatment of psoriasis [51].

Th17 cells, neutrophils, mast cells, Nk cells, and B cells are the source of IL-17 [52], The IL-17 family has 6 members (IL-17A – IL-17F) that bind to specific receptors [53].

In macrophages and fibroblasts, IL-17 induces the expression of pro-inflammatory molecules (IL-1p, IL-6, GM-CSF, TNF-alpha) [52].

Having a pro-inflammatory role, it can cause autoimmunity in the immune system, which has been demonstrated for rheumatoid arthritis, psoriasis, and inflammatory bowel disease [53].

IL-17 is involved in the inflammatory process from metabolic disorders, such as hepatic steatosis and arteriosclerosis [54] so IL-17 antagonists can also intervene in the improvement of comorbidities, not only in the treatment of psoriasis [55].

IL-22 is part of the same family of cytokines as IL-10, and the active form is a monomer that binds to its specific receptor, located at the level of epithelial cells and fibroblasts of various cells [56]. It consists of heterodimeric subunits (IL-22R1 and IL-10R2) [57].

IL-22 is produced by CD4 (Th1, Th17, Th22) and CD8 lymphocytes, innate lymphoid cells, and NK cells [58].

The transcription factor RORγt is essential for IL-22 production because CD4 + cells secrete IL-22 only in the presence of this receptor [59].

The serum level of IL-22 is correlated with the activity of the disease [57] and in the skin with psoriasis lesions, the level of IL-22 is increased [58]. This causes keratinocytes to migrate, preventing their differentiation, and leading to the thickening of the epidermis [59]. Therefore, IL-22 could represent a potential target for the treatment of psoriasis [57].

IL-12 is produced by dendritic cells, macrophages, and neutrophils, being a heterodimer formed by the p35 unit and the p40 unit [62]. Its receptor is mostly found on T cells and N cells [65] and consists of IL-12 Rbeta 1 and IL-12Rbeta2 subunit [63]. The binding of IL-12 to the receptor activates the JAK/STAT pathway [67]. Although IL-12 increases IFN-gamma and TNF-alpha [68] molecules involved in the pathogenesis of psoriasis, an increased level of the p35 subunit was not detected in the skin of patients with psoriasis [69], and targeting the p40 subunit exerted its effects by inhibiting IL-23 [70].

The main sources of interferon-gamma - type 2 interferon (IFN-γ) are CD4+ and CD8+ cells, NK cells, but also antigen-presenting cells and B cells [69]. It is involved in antiviral and antibacterial defense [67]. The IFN-gamma receptor consists of two IFNGR1 chains and two IFNGR2 chains responsible for signal transduction [71], which leads to the activation of the JAK/STAT signaling pathway [72]. The serum level correlates with the activity of the disease, being higher in patients with psoriasis [70]. Greater decreases in serum IFN-gamma are associated with longer periods of disease remission [67], but anti-IFN-gamma therapy has not demonstrated efficacy on psoriasis lesions [70].

The role of TNF alpha in the inflammatory mechanisms of psoriasis

TNF-α is produced by macrophages, monocytes, keratinocytes, and lymphocytes, being a pro-inflammatory cytokine [72], involved in both acute and chronic inflammation [71], with an antibacterial and antitumor role [70].

Receptors for TNF are found in all nucleated cells [69] and are formed by two main isoforms: TNFR1 and TNFR [73].

TNF alpha is involved in the proliferation of CD4 cells [72], in the production of chemokines and cytokines [74] (IL-1), and is also involved in the process of apoptosis in certain types of cells [73].

The level of TNF-alpha correlates with disease activity [71], and TNF-alpha inhibitors have proven effective in the treatment of plaque psoriasis [72].

INFLAMMATORY CELLS IN PSORIASIS

Keratinocytes and cells of innate immunity in the skin

At the level of the skin, which is the largest organ of the body, consisting of the epidermis, dermis, and hypoderm [3], there is a large number of cells with various roles.

In psoriasis, the interaction between cells of the innate immune system (macrophages, neutrophils), cells belonging to adaptive immunity (T and B cells), and resident cells (keratinocytes, melanocytes) support chronic inflammation [73].

In the early stage of inflammation, an important role is played by dendritic cells, which are antigen-presenting [75]. The mechanism by which these cells are activated is incompletely elucidated, but it seems that there are certain microbial peptides, such as LL37, and S100, released by keratinocytes [76]. In psoriatic skin, these peptides are overexpressed and bind to the DNA of damaged cells, which causes dendritic cells to be activated to produce IFNα [77]. It (IFNα) causes the activation of myeloid dendritic cells [75].

Activated dendritic cells transform into antigen-presenting cells to be able to interact with naïve T cells and begin to produce large amounts of TNF-alpha, IL-23, IL-6, and IL-12 [77].

These cytokines activate the inflammatory cascade by recruiting neutrophils to the site of inflammation [78] and the proliferation of keratinocytes [79].

Keratinocytes, in turn, produce antimicrobial peptides [74], cytokines (IL-6, TNF-alpha), and chemokines (CCL20, CXCL5, CXCL9, CXCL10) [76].

IL-36, secreted mainly by keratinocytes and dendritic cells [73], accumulates neutrophil granules, present in large numbers in psoriatic skin [77]. IL-36 binds to its receptor IL-36Ra [78] and is involved in the transcription of other inflammatory mediators, by activating NF kappa B [79]. Also, IL-36 increases inflammation through its interaction with other inflammatory cytokines, such as IL-17 [79]. Some data suggest that decreasing the number of neutrophils significantly improves inflammation [76].

Macrophages are also antigen-presenting cells [75]. They derive from monocytes [77] and are involved in the occurrence of psoriasis inflammation [78], being an important source of TNF-alpha [77].

Within the innate immune system, cells without antigen-specific receptors (ILCs) are involved in antimicrobial defense and create a balance between pro- and anti-inflammatory factors [80].

ILC 3 can produce IL-17 and IL-2 [81], and their number decreases in the affected skin during the remission period of the disease [80], emphasizing the involvement in the pathogenesis of psoriasis, which requires additional data [81].

T cells

T cells have an important role in the defense against pathogens, and in the pathogenesis of psoriasis, there is an interaction with a central role between T cells and dendritic cells.

Dendritic cells release cytokines such as IL-12 and IL-23 that promote Th1, Th17, and Th22 responses.

At the epidermal level, T helper cells support keratinocyte hyperproliferation, leading to decreased apoptosis.

By carrying out human skin transplantation in SCID immunodeficient mice, followed by the injection of CD 4 T cells from patients with psoriasis, the role of these cells in the pathogenesis of psoriasis was demonstrated.

Th 1 (CD4+) cells produce large amounts of TNF-alpha and IFN-gamma involved in triggering psoriasis.

In mice with IL-17 receptor deficiency, skin inflammation is reduced, emphasizing the importance of IL-17 in the occurrence of psoriasis lesions.

Thus, elevated serum levels of IL-17 and increased expression in lesions are typical features of psoriasis.

After it was demonstrated that IL-23, produced by dendritic cells, is involved in the development of Th17, it became obvious that the IL-23/Th17 axis has an important role in the pathogenesis of psoriasis.

B cells

B cells are involved in the adaptive immune response through antibody production and antigen presentation [23].

Using a model of intestinal inflammation, Mizoguchi et al. [58] in a model of intestinal inflammation, showed that B cells produce IL-10 and thus have a protective role against inflammation.

Also through the secretion of IL-10, B regs cells are involved in alleviating various allergic and inflammatory diseases [82]. They do not represent a distinct lineage of B cells but are rather a subset of them [81]. It is not elucidated which factors are involved in the development of B cells in a type B regs [80].

The B regs cell population is characterized by the presence of CD5+CD1d hi on the surface [81].

Other subsets of B cells involved in the production of IL-10 are those in the marginal zone – CD19+CD21 hiCD23-CD24hi and CD138+ plasma cells [80].

Compared to T cells and studies regarding their role in the pathogenesis of psoriasis, in the case of B cells, data are limited regarding the involvement of these cells in psoriasis, as they rarely appear in lesional skin [83].

The decrease in the number of B lymphocytes in patients treated with anti-CD20 (Rituximab) for other autoimmune diseases led to the appearance of psoriasis skin lesions in individual cases [84].

B cells secrete inflammatory cytokines such as IL-6, IL-4, and IFN-gamma, being key effector cells [83].

Also, in a recent study, it was demonstrated that a large number of IL-6-producing B cells are found in inflamed mouse skin [80]. Blocking IL-6 resulted in reduced inflammatory symptoms [84].

DISCUSSION

In the case of mild psoriasis, the inflammatory process is confined to the skin, on the other hand, a more extensive active disease should be regarded as a systemic inflammatory disease, impacting internal diseases, including arthritis and metabolic syndrome [88].

Patients suffering from moderate to severe forms of psoriasis have increased serum levels of multiple proinflammatory cytokines, including TNF-a, IFN-c, IL-6, IL-8, IL-12, IL-17A, and IL-18 [89].

All the subtypes of T cells involved in the pathogenesis of psoriasis are also involved in atherosclerosis [90]. Sherlock et al. demonstrated that IL-23 drives inflammation in the aortic root through the activation of CD3+CD4−CD8− T-lymphocytes [91].

TNF alpha plays an important role in the inflammatory pathways of metabolic syndrome, diabetes, and cardiovascular disease. TNF alpha inhibitor therapy is associated with a lower risk of major adverse cardiovascular events (MACE) independent of traditional cardiovascular risk factors [92]. Recent research shows the importance of Th17 and other IL-17-producing cell types in the pathogenesis of cardiovascular events [90].

We lack large well-designed studies which prove the improvement of comorbidities by treating psoriasis with biologics.

In short term, there is evidence that early treatment with biologics reverses damage caused by inflammation. New biomarkers and early diagnosis help healthcare workers in better evaluation of patients' responses to systemic therapies [93].

CONCLUSIONS

Psoriasis is a recurrent, chronic, T-cell-mediated, polygenic disease characterized by erythematous squamous lesions in specific body sites. The pathogenesis of psoriasis is complex and still undergoing study. Biologic therapy is the key to reversing inflammations and preventing associated comorbidities.

Abstract: *Angiosarcoma is a malignant tumor derived from the endothelium of the blood and lymphatic vessels. Its aggressive behavior results in a poor prognosis for the patients. Radiation-associated angiosarcoma is a rare recently described particular subtype of angiosarcoma best shown in patients after treatment of breast cancer. The latency period of development is approximately 8 years, thus the 5-year standard follow-up after mammary neoplasm therapy needs to be extended up to 10 years. Radiotherapy is an independent risk factor for angiosarcoma development. Rapid diagnosis is essential for prompt therapeutical intervention to improve the patient's prognosis. The importance of early diagnosis is emphasized by a case of a 54 years old woman, with a diagnosis of breast cancer treated by sectorectomy and radiotherapy 7 years prior, presenting to our Dermatology Department for the recent occurence of erythemato-violaceous cutaneous patches on the area subjected to radiotherapy.*

Keywords: *angiosarcoma, radiation, radiotherapy, breast cancer, conservative surgery, follow-up*

INTRODUCTION

Angiosarcoma is a malignant tumor that originates in the endothelium of the blood and lymphatic vessels [1]. It usually develops in the skin, soft tissue, breast, or liver [2]. It comprises 1-2% of the soft tissue sarcomas that appear in humans [3], it is uncommon and affects mostly Caucasian men, with the highest incidence in adults over 70 years.

When it comes to younger ages such as children or adolescents, angiosarcomas are rare and are prone to develop in viscera or nearby, usually the heart, or they are associated with other conditions such as immuno-suppression, chronic radiodermatitis or lymphedema [4].

Risk factors associated with angiosarcoma include chronic lymphedema, radiation history, carcinogens (eg vinyl chloride, arsenic), and specific familial syndromes [3].

Angiosarcomas cells have endothelial differentiation and they clone while undergoing a malignant transformation. Unlike other sarcomas, angiosarcomas have a different upregulation of the genes responsible for the vascular receptors [4]. In angiosarcomas that have been induced by radiation or lymphedema, the amplification of MYC is high which in the end leads to the downregulation of thrombospondin-1, a protein that inhibits angiogenesis [4]. MYC is overexpressed in patients with radiation-induced angiosarcoma and this can help distinguish it from primary angiosarcoma [5]. Angiosarcomas can be well- or poorly differentiated; in the first case, one can observe vascular channels that are not regular in shape, they are lined by endothelial cells and they dissect the fibers of collagen; the latter has ill-defined vascular spaces, the cells are spindled, polygonal, epithelioid and round and they show multiple mitosis and big nuclei [1].

Immunohistochemistry is used when diagnosing less differentiated angiosarcomas. The cells express vascular as well as endothelial antigens such as Factor-VIII, CD31, CD34, and VEGF. CD31 is seen in more than 50% of the cases and has great sensitivity and specificity [3]. Recently, there has been used a marker called ERG, which is a member of the ETS family of DNA-binding transcription factors and which offers greater sensitivity and specificity for endothelial cell differentiation

[1].

PATHOGENESIS AND TYPES OF ANGIOSARCOMAS

The mechanism through which angiosarcoma may appear in chronic lymphedema is not well known, but theories postulate that some carcinogens build up in the lymphatic fluid and because the lymphatic network is lost, the affected area is spared by the immune system and this fact can furtherly favor the neoplastic modified cells.

An independent risk factor for the development of angiosarcoma is radiotherapy which is best shown in patients with breast cancer [4].

There are essentially 3 instances for the occurrence of cutaneous angiosarcoma: idiopathic angiosarcoma of the scalp, face, and neck, angiosarcoma associated with chronic lymphedema (Stewart-Treves syndrome), and post-irradiation angiosarcoma. Some authors describe a fourth type which occurs in any other settings than the previous ones [1].

Angiosarcoma of the scalp, face, and neck is most frequent in elderly individuals. Men are two times more affected than women. The lesion begins as a bluish macule that can be confused with a bruise.

Angiosarcoma associated with chronic lymphedema is also called Stewart-Treves syndrome and this type is seen in areas with long-lasting lymphedema as is the case of the upper arm after the patient underwent a mastectomy. The tumor develops 11-22 years after surgery, having though a low incidence of 0.45% of the cases, but a poor prognosis [6]. Other instances of chronic lymphedema may be parasitic infections or congenital lymphedema [3].

Post-irradiation angiosarcoma is a vascular tumor that appears in sites that have been irradiated in the past. If the affliction for which the patient has received radiotherapy was benign, the average time for angiosarcoma to develop is 23 years, but if the condition treated with radiation was malignant, then the time reduces to only 12 years [6].

The fourth type is uncommon and may appear for example in benign vascular tumors, in cases of immunosuppression after organ transplantation.

RADIATION ASSOCIATED ANGIOSARCOMA

The angiosarcomas that arise in areas of previous radiation sites are difficult to be differentiated from atypical vascular lesions. Sometimes even histologically, the diagnosis can be challenging since well-differentiated angiosarcomas which exhibit only minor cytologic atypia despite their aggressive behavior, may be similar to microcystic lymphatic malformation. Also histologically, the angiosarcoma must be differentiated from other vascular neoplasms such as PILA (papillary intra-lymphatic angioendothelioma), RHE, epithetlioid hemangioendothelioma, KHE (Kaposiform hemangioendothelioma) [4].

Imaging tools such as CT, and MRI are helpful, but to have a precise diagnosis for angiosarcoma, histologic examination and immunohistochemistry of the tissue confirm the disease.

Post-irradiation angiosarcoma is not seen very often [1]. It is considered a late severe complication of radiotherapy [7]. The majority of cases emerge in the skin after it has been irradiated for breast cancer, or not so frequently, for a neoplasm of the internal organs [1]. Post-irradiation angiosarcoma has a cumulative incidence of 0.9-3.2 per 1000 cases of mammary neoplasm. In terms of prognosis, a 5-year survival rate lies between 27 to 48% [8]. If the patient had radiation therapy for breast cancer, the period after which a sarcoma in this area may appear is 5-10 years and this means that the usual 5-year follow-up needs to be extended [3]. It appears that other radiation-induced sarcomas take more than 10 years to develop [9]. Some studies link the usage of radiation in high doses with the incidence of angiosarcoma [3]. In the case of breast angiosarcoma, the latest population-based studies have shown the risk to be about 0.1%. It has been hypothesized that the replacement of radical mastectomies with conservatory surgery has led to secondary angiosarcomas in the mammary gland [10]. Breast angiosarcoma can be categorized into primary (de novo) if it develops without any known trigger, or secondary if it appears at the site of previously irradiated integument [8].

It appears that in the last few years, of all the subtypes of sarcomas of the breast induced by radiation, angiosarcoma had the highest occurrence [10].

In a retrospective Dutch population-based study from 2019 of 296,577 patients with angiosarcoma after breast cancer treatment (1989-2015), the median follow-up after diagnosis of breast cancer was 7.7 years, and the median age when diagnosed with angiosarcoma was 58 years. Of the 184,823 patients that received radiotherapy, only 209 had angiosarcoma of the breast and/or chest wall. As a note, angiosarcoma did not occur in any of the patients that did not receive radiotherapy (111,754). The median period between breast neoplasm treatment and the appearance of post-radiotherapy angiosarcoma was 8 years. In this study, 5- and 10-year survival rate was 40.5% and 25.2%, respectively, regardless of the type of treatment (surgery alone, surgery and radiotherapy combined sometimes with hyperthermia, chemotherapy, and radiotherapy). The inclusion of radiotherapy compared to only surgery had not shown a significant survival [7]. Another study from 2013, that evaluated 48 patients with angiosarcoma treated between 1990 and 2004 (7 with breast cancer) showed a 7 years latency period for angiosarcoma of the breast. [11].

Clinical presentation of cutaneous angiosarcoma includes single or multiple red, bluish or violaceous macules, patches, and nodules, that can further ulcerate or present intra-tumoral hemorrhage [6].

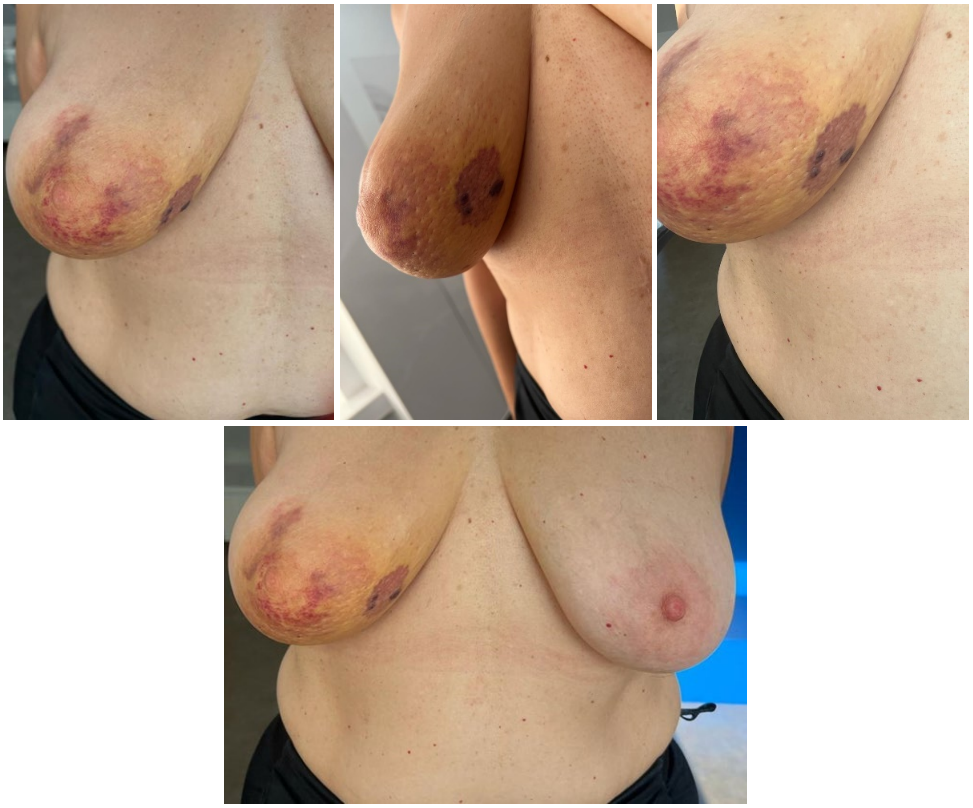
The 2022 diagnostic criteria for radiation-associated angiosarcoma are a) sarcoma that develops in a previously irradiated field or the tissue volume comprised in the 5% isodose line; b) minimum 4 years between radiotherapy and the arising of the angiosarcoma; c) histological difference between primary neoplasm and secondary sarcoma; d) the exclusion of patients with cancer syndromes [5].

The prognosis is poor because angiosarcoma is an aggressive tumor; patients' survival rate without treatment is between 6 months and 2 years after diagnosis [6]. If it is a low-grade tumor, it behaves similarly to atypical vascular lesions, but a high-grade angiosarcoma is aggressive, has violent growth, and local recurrences arise after a few months [9]. However, with an incidence so low, one can assume that it is worth risking the arising of an angiosarcoma in a patient with breast cancer for the benefit of radiotherapy on the primary neoplasm [8].

Treatment consists of surgery, radiotherapy, and chemotherapy as options, but the choices and results vary on tumor size, location, and type, and last, but not least, resectability [3]. Currently, the main choice is surgical removal [8]. For localized angiosarcoma, the mainstay of the treatment is surgical resection along with adjuvant radiotherapy. Recurrences are difficult to avoid; chemotherapy is the first option in case of metastatic angiosarcoma [3]. The recurrence rate of post-radiation angiosarcoma of the breast is high (96%) and metastases are most often found in the lungs and liver and they can coexist with the local recurrence or appear soon after [8].

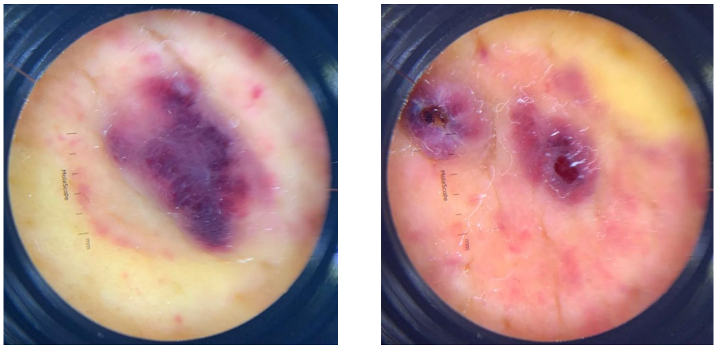
In a case of a 54-year-old woman who was referred to our clinic for ecchymotic and purpuric macules localized on the right breast, postradiotherapy angiosarcoma was diagnosed based on clinical aspect, history, histology, and immunohistochemistry. She had a previous history of sectorectomy for breast cancer 7 years prior and she also underwent radiotherapy. Clinical examination identified well-defined ecchymotic and purpuric macules, oval or with irregular polycyclic borders, 1-3 cm diameter; a similar macule located in the lower-inner quadrant, 4 cm diameter, with purple nodules on the surface, resembling Kaposi sarcoma (Figure 1).

Figure 1: Clinical aspect of the breast lesion



The lesions appeared 2 months before presentation, with progression in terms of dimensions and the number of lesions. The dermoscopic examination showed a combination of red, blue, and purple: a violaceous hue of the lesion that had purple clods with white structures, red and blue areas, and reddish-brown crusts that covered the central part of the nodules (Figure 2).

Figure 2: The dermoscopic examination



Skin biopsy of two sites was performed: a cutaneous nodule from the lower-inner quadrant of the right breast and a cutaneous fragment from the upper-outer quadrant of the right breast. The histology examination revealed: the first site showed ill-defined tumoral proliferation made up of randomly located oval/fusiform cells with elongated nuclei or grouped in short anastomotic bundles that defined small vascular spaces or intracytoplasmic slits without walls, some of them containing blood; moderated lymphoplasmacytic infiltrate and hemosiderin associated deposits. The second site of the biopsy had the same histopathologic description (Figures 3 and 4).

Figure 3: Dermal vascular proliferation, mimicking Kaposi sarcoma (HE X 10)

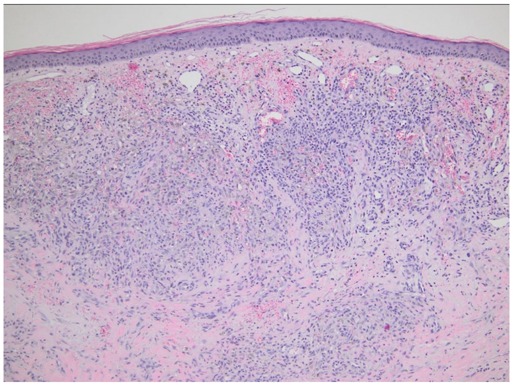


Figure 4: Dermal vascular proliferation, mimicking Kaposi sarcoma (HE X 20)

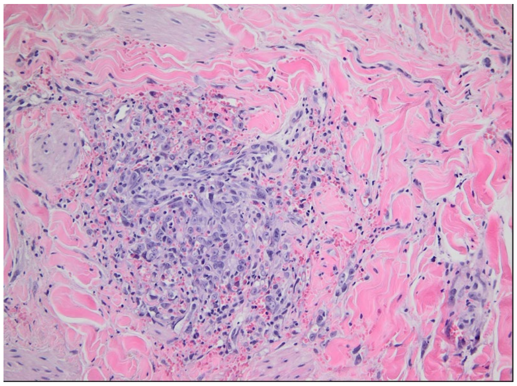

Was then performed immunohistochemistry tests for a positive diagnosis. These tests showed on both blocks HHV-8 negative and ERG and SMA positive, but c-MYC positive on the second piece of tissue (Figures 5-7).

The conclusion was that of a postradiotherapy angiosarcoma. The patient was then referred to Oncology Department for further investigations and therapeutic intervention.

Figure 5: C-MYC positive within numerous tumor nuclei

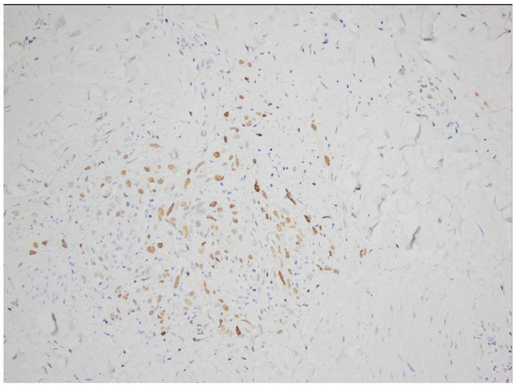

Figure 6: SMA positive within scattered tumor cells

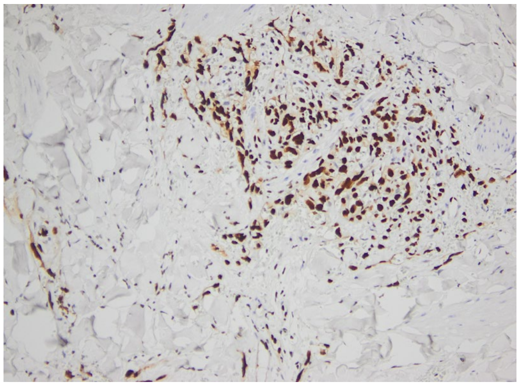

Figure 7: ERG positive within numerous tumor nuclei

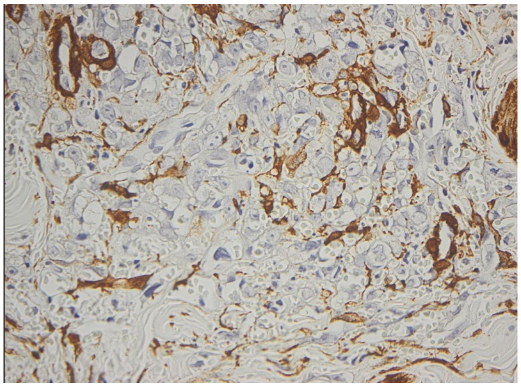

CONCLUSIONS

- Radiotherapy is an independent risk factor for the development of angiosarcoma, best shown in patients with breast cancer.
- Post-irradiation angiosarcoma has a cumulative incidence of 0.9-3.2 per 1000 cases of mammary neoplasm so it is a rare complication of radiotherapy, proving to be a challenging clinical diagnosis.
- The diagnosis of angiosarcoma can also be histologically challenging – it can exhibit only minor cytologic atypia in well-differentiated cases; immunohistochemistry testing is essential for differentiation from other types of sarcoma (including Kaposi sarcoma).
- The average period between breast neoplasm treatment and the appearance of post-radiotherapy angiosarcoma is 8 years.
- Prognosis of RAASB is poor, 5-year survival rate lying between 27 to 48% and thus it needs rapid diagnosis and therapeutic measures.
- 5-year standard follow-up after breast cancer needs to be extended up to 10 years to capture the development of an angiosarcoma.

Abstract: *Pheochromocytomas are rare neuroendocrine tumors that frequently have genetic involvement and can present a particular risk in terms of the anesthetic-surgical procedure. Current worldwide medical recommendations state that laparoscopic adrenalectomy is the conventional treatment for pheochromocytoma, however, the ideal surgical strategy is still being developed as specialized surgeons gain experience with these rare tumors. The study's purpose was to thoroughly evaluate our film library and identify the best surgical steps that represent our standardized procedure. We developed a comprehensive set of surgical critical strategies for either a left or right adrenalectomy, providing helpful advice on patient positioning, port placement, the adrenal gland approach, as well as other surgical methods specifically designed for tumor mobilization and dissection. The current paper aims to synthesize our clinical experience in terms of preoperative preparation, patient positioning, intraoperative complications, causes of conversion, and specimen extraction. The main conclusions concern both the best surgical approach and the importance of surgical experience in the clinical management of these rare tumor types.*

Keywords: *pheochromocytomas, laparoscopic adrenalectomy, surgical strategy*

INTRODUCTION

Pheochromocytomas are relatively uncommon tumors often with genetic aggregation that is accompanied by a high risk of overall morbidity and mortality, especially during surgical procedures precipitated by important blood pressure and heart rate variations. Although laparoscopic adrenalectomy has become a standard procedure for pheochromocytoma, the optimal approach continues to evolve as surgeons develop expertise in this pathology.

MATERIALS AND METHODS

Our experience starts almost 20 years ago, counting 436 laparoscopic adrenalectomies, from which 96 were performed for pheochromocytoma. We systematically reviewed our video database and highlighted the best surgical steps that exemplify our standardized approach.

RESULTS

From our experience, we managed to synthesize detailed surgical key steps for the overall procedure when performing left or right adrenalectomy, offering valuable tips starting from the patient positioning, and port placement and continuing to the adrenal approach, along with different strategies specifically tailored for pheochromocytoma mobilization and dissection. Taking into consideration our experience in dealing with the challenges of this procedure the current article aims to lead to improvement of overall outcomes for this procedure.

Preoperative preparation

From the anesthesiologist's point of view, surgical resection of pheochromocytoma can be divided into two phases based on the ligation of the tumoral blood supply [1]. Communication between the surgeon and the anesthesiologist regarding the surgical steps, in particular the ligation of the central adrenal vein, allows a proactive attitude, foreseeing the eventual intraoperative hemodynamic variations.

The first part of the procedure refers to all the surgical and anesthetic steps before ligation of the central adrenal vein in which severe episodes of cardiac arrhythmias and hypertension can occur [1].

The second part refers to all the surgical events that follow the central adrenal vein seal and it might be characterized by a sudden decrease of arterial blood pressure and in intravascular volume that might require vasopressor support [1].

Keeping in mind the possible cardio-circulatory outcomes during this surgical procedure, large-bore venous access should always be obtained [2], the guidelines also recommend continuous intraarterial blood pressure monitoring for all patients with pheochromocytoma or at least for those with persistent preoperative hypertension [3–5].

Adding a central venous catheter allows secure and effective administration of vasoactive medication to promptly counterbalance the hemodynamic variations, especially since there are no accurate predictors of which patients are most likely to need central administration of vasopressors [2,4].

In our experience, the availability of 2 large-bore venous access associated with good preoperative management with stress minimization and anxiolytic administration, decreases the sympathetic nervous stimulation, that might trigger a hypertensive crisis [6,7], was enough to ensure rapid and effective administration of intraoperative drugs. Frequent non-invasive blood pressure measurement (every 3 minutes) and close communication with the surgeon regarding the current, the following, and the particularities of the ongoing surgical steps supply all the data needed to fine-tune vasoactive drug administration even without intra-arterial continuous blood pressure monitoring.

Although not routinely recommended, at the beginning of our experience we chose to perform a mild bowel preparation the day before the surgery (polyethylene glycol), a practice that we later abandoned as we saw no intraoperative benefit in terms of bowel injury or postoperative bowel movements. More than that, some of the cases presented a distended lumen at the time of surgery, especially for the left colonic flexure, and this was disturbing the surgical dissection.

Patient positioning

Our experience refers only to the transperitoneal approach mainly due to the familiarization with the peritoneal cavity as general surgeons. In all our cases we used the lateral trans peritoneal approach because it usually offers a larger surgical field that is particularly useful in the case of large tumors such as pheochromocytomas and morbidly obese patients.

The standard patient position for laparoscopic adrenalectomies is in contralateral decubitus [8,9] with the possibility of a backward tilt up to 30° [5]. After anesthesia induction, a nasogastric tube (especially useful in left-sided adrenalectomies), and urinary catheter insertion, the patient is placed in lateral decubitus. Prevention of contralateral brachial plexus injury was done using a soft roll under the contralateral axilla. The other arm is can be elevated and secured on an elevated arm board [8] but, in our experience, we placed the ipsilateral arm slightly bent, in a relaxed position over the other one without needing rigid support or any other fixation method.

Keeping in mind the unpredictable hemodynamic events that characterize pheochromocytomas during adrenal surgery, the patient's position has to offer both good access to the tumor and also the possibility to finish the surgery openly due to conversion in an emergency setting. The umbilicus is placed above the surgical table breakpoint that is next flexed and tilted in an anti-Trendelenburg position until the ipsilateral flank contour is stretched to a straight line which we position parallel to the horizontal line. Over-flexing the operating table can cause supplementary tension of the abdominal wall thus causing less compliance, less working space, and consequently need for increased pneumoperitoneum pressure [8]. These patient position landmarks provide a maximum distance from the anterior superior iliac spine and costal margin offering a large operating field and increased ergonomic for the surgical team even for large tumors – the patient “needs to open” as much as possible the space between rib’s rim and the iliac crest. Depending on the high conversion probability (large tumoral size, retrocaval positioning, and hemodynamic variability) we tilted the patient back up to 30° using shoulder and hip supports. The patient’s legs are a little bit flexed to avoid stretching the crural nerve. Additional fixation was achieved using cloth straps at the hip and leg level.

According to the literature, trocar placement is variable. All ports are inserted at least 2 cm from the rib’s margin. Pneumoperitoneum is achieved in open maneuver, and then the first 10 mm trocar is inserted between the anterior axillary line and midclavicular line, depending on the exposure of the operating field (first, we palpate the inferior edge of the liver and – when is possible – the fundus of the gallbladder, then we decide to insert the trocar laterally to the gallbladder with a parallel direction to the trajectory of the inferior vena cava). Other three 10 mm trocars are inserted under direct visualization equidistant from each other (at least one hand distance), in the lateral border of the rectus sheath, another in the midaxillary line, and for retraction, one below the xiphoid process [10]. In all the laparoscopic adrenalectomies performed in our hospital, we used the Veress technique for the pneumoperitoneum, and the first skin incision was made in the midclavicular line at 3-4 cm from the rib’s margin. Only in obese patients, pneumoperitoneum was realized at 2 cm from the rib margin because CO_2 abdominal distension would move the incision further caudally causing a suboptimal visualization of the surgical field. All surgeries were performed with 4 trocars (we didn't experience a surgical adrenalectomy with 5 or more additional trocars): below xiphoid process for retraction, on the axillary line below the 10th rib (12 mm – used also to extract the specimen), and one at the half distance between the sub-xiphoid and optic trocar. The peritoneal space is insufflated to 12 mmHg using slow or medium flow insufflation as it is known that, intra-abdominal insufflation during laparoscopic pheochromocytoma excision may cause an increase in serum catecholamines [5,11] – Consequently, we strongly advise for taking enough time to realize the proper intra-abdominal pressure using small quantities of CO_2 inflated in at least 5 minutes (break times can be used!). During this time, the blood pressure of the patient should be carefully observed by the anesthesiologist and a trend to increase should be instantly corrected but not using too many anti-hypertensive drugs (risk for severe hypotension and rebound). Usually, the failure of this operative time is solved by conversion to open surgery, with rapid recovery of the blood tension being noticed with no major anesthesia intervention.

It is known that during surgery for pheochromocytoma, there is a risk of a hypertensive event due to catecholamine secretion – it could be beneficial for the patient to use a decreased level of pneumoperitoneum – like 11 mmHg, even 10 mmHg – if the working camera is allowing you proper movements of the instruments. Many surgeons highlighted that early ligation of the adrenal vein is an important goal in adrenalectomy, but studies have shown that delayed vein ligation does not appear to cause significant hemodynamic variation during laparoscopic adrenalectomy for pheochromocytoma [12,13] and taking into consideration that the dissection of the adrenal vein as the first step of the adrenalectomy, can be more demanding in case of large size adrenal lesions such as pheochromocytomas, we did not routinely approach the adrenal vein first (unless it was identified from the very first beginning), and we did not encounter intraoperative cardiovascular complications. Laparoscopy offers a real-time surgical overview to the anesthetic team that can anticipate when the adrenal vein is ligated and take steps to avoid cardiopulmonary complications.

Even from the insertion of the camera, a full video inspection of the peritoneal cavity should be done to evaluate the availability of other trocar entry sites. The presence of intraperitoneal postoperative adhesions can change the trocar order so that the operating field and other trocar entry sites can be conveniently exposed. In particular, placement of the lateral port in left adrenalectomies requires, in most cases mobilization of the splenic flexure and descending colon incising the peritoneum along the white line of Toldt. The viscera surrounding the adrenal gland are inspected for invasion: the spleen, the diaphragm and the greater gastric curvature (on the left side) and ascending colon, the liver, the right kidney, the diaphragm, and the duodenum (on the right side) are inspected and if there are suggestive signs of malignancy, conversion is mandatory [8]. Before beginning the laparoscopic adrenalectomy we should keep in mind that pheochromocytomas are larger than other adrenal tumors and, in our experience, they also have a frail consistency with a thin capsule and an increased number of arteries and veins that easily bleed on manipulation. This is the reason we advise having proper laparoscopic equipment and also alternatives to ensure good hemostasis and vessel sealing as well as to strictly follow the rule of "dissection of the body from the gland instead of dissection of the gland from the body" (Prof. J Marescaux, Strasbourg, France – off-the-record).

On the right side, while the liver is retracted cranially and medially so that the peritoneal reflection is seen and the left-right triangular ligament is tensioned and divided; the peritoneum is incised along the liver as far on the diaphragm so that the right lobe of the liver gently falls away medially. The posterior peritoneum is incised along its reflection on the inferior liver margin. The inferior vena cava (IVC) is identified and the peritoneum along its lateral margin is incised until it meets the hepatic parenchyma. The literature defines the caudal limit for the peritoneal division along the IVC as the superior edge of the renal vein [14] in our experience identifying this landmark might require unnecessary touching of the pheochromocytoma, especially in patients with well-represented retroperitoneal fatty tissue. When dealing with pheochromocytoma we use the macroscopic inferior border of the adrenal tumor as a landmark for inferior peritoneal division, as these tumors tend to be larger, carefully not to damage the inferior arm of the adrenal gland.

On the left side once the hepatic flexure and descending colon have been retracted medially by following the space between the Gerota's fascia and the mesocolon [8]. The next step ensures a good mobilization of the spleen and is carried out by division of the phrenicosplenic ligament starting at the posterior and inferior margin of the spleen and continuing cranially until the fundus of the stomach is visualized. Although the literature mentions visualization of the left diaphragmatic crus as the end landmark of this dissection [8], in our experience this was rarely needed. Medial mobilization of the spleen during this step can be performed with gentle retraction or, as some authors recommend, leaving a 2 cm peritoneal margin attached to the inferior margin of the spleen to grasp [8]. Usually, this is the moment when accidentally puncture of the splenic parenchyma is performed due to aggressive manipulation of the laparoscopic instruments – minor bleeding can occur and immediate hemostasis should be performed using hemostatic agents like oxidized regenerated cellulose or other topical fibrin sealant patch (sometimes, when a simple injury of the spleen capsule is noticed, it is enough to apply a pad pressure onto the injured area for a few minutes). Once the spleen is fully mobilized it will fall medially along with the tail of the pancreas exposing the lateral edge and anterior portion of the left adrenal gland [9]. Correctly fulfilling this surgical step ensures access to the right dissection plane thus avoiding blind dissection into retroperitoneal fatty tissue which is prone to excessive bleeding and capsular breaking, forbidden when resecting pheochromocytomas.

Partial adrenalectomy avoids the need for life-long hormone replacement and it is usually useful for patients with bilateral gland involvement. This procedure is performed in small tumors located on the periphery of the affected adrenal limb. Performed in pheochromocytoma has a high risk for intraoperative hypertensive crisis due to tumor manipulation and thus early identification of the adrenal vein is mandatory before partial resection [15]. For partial adrenalectomy to be feasible the remnant gland to have a good vascularization, so laparoscopic ultrasonography to evaluate the adrenal gland viability must be recommended [16]. Because of the risk of bleeding in partial adrenalectomy, it is preferred safety surgery and total adrenalectomy be performed.

Once the periglandular dissection is started it is important to keep in mind a principle postulated even from the first adrenalectomies, and demonstrated in later studies: a mean increase in plasmatic catecholamines up to 34-fold during tumor manipulation [17-19]. To minimize hemodynamic instability, these techniques require minimal to no direct manipulation or compression of the tumoral gland [5], achieved in many cases by gentle retraction of the surrounding viscera or tissue such as the kidney, pancreas, and liver or by using periglandular fatty tissue, the Gerota’s fascia and/or the disconnected vein stump, to manipulate the gland accordingly. Comparing pheochromocytoma ablation with other types of adrenal tumors, it is mandatory to respect the principle of “dissecting the patient away from the tumor” to achieve this important goal [20]. In large tumors with which we encounter technical difficulties prompt conversion has to be taken into consideration to reduce the patient's risk for capsular disruption and following iatrogenic disease recurrence [5] or even pheochromocytomatosis [14]. As mentioned before, pheochromocytomas have numerous tributary vessels that combined with the frail vascular wall and increased circulatory catecholamines represent the optimal recipe for possible uncontrollable bleeding, so achieving a proper vessel seal before tissue dividing is mandatory even with the usage of clips as a complementary method to the electrocoagulation and sealing devices [5].

For the right-sided adrenalectomy, the lateral border of the IVC continues to be the main landmark during the procedure allowing lateral retraction of the adrenal gland and thus exposing the central adrenal vein. Even though it is more demanding, many authors concluded that once the peritoneum is incised, as mentioned before, the tumoral gland should be approached first on the medial border – detaching the tumor from the IVC, exposing, clipping, and dividing the central adrenal vein [8]. The dissection continues along the inferior border of the adrenal gland and might include the peri-adrenal fat. The adrenal is gently lifted and the posterior aspect is released and then the lateral one. The final step is detaching the superior border of the tumor [8]. We share the opinion that first freeing the inferior and posterior aspect of the gland assures enough mobility to safely push the gland laterally, without manipulation or grasping, increasing the space to the IVC, exposing the central adrenal vein, and more important, pulling the adrenal tissue situated posterior to the IVC. While this approach carries a higher risk of capsular breaking when beginning the dissection, it offers more control and better retraction in dealing with the main vascular pedicle and retro-caval adrenal tissue. The dissection continues cephalad until the medial side of the gland is released and further on the superior edge.

Once the central adrenal vein is secured, we can better manipulate the tumoral gland. In large tumors, some authors recommend starting the dissection from the lateral and superior border of the tumor and then moving inferior to the IVC [8].

For the left adrenalectomy, it is generally accepted that the dissection begins along with the medial border proceeding from the upper to the lower adrenal pole, keeping close to the posterior muscular plane. This maneuver allows lateral rotation of the adrenal and exposes the left adrenal vein that will be ligated early in the dissection. During the dissection of the medial border of the adrenal gland, the inferior diaphragmatic vein might be encountered and it represents a landmark for the central adrenal vein. Particularly in pheochromocytomas, starting the dissection from the lateral border should be avoided since it will cause the gland to rotate inferiorly and medially thus requiring increased manipulation and pulling the adrenal gland, in order to access the central adrenal vein. After securing the central adrenal vein, the gland is lifted and the dissection continues at the posterior and lateral aspect of the gland, leaving the upper adrenal pole to be approached as last surgical gesture [8,14].

Several factors as the lack of major anatomic landmarks, the relative profound in the retroperitoneal fat of the left adrenal gland, with the main vein within the retroperitoneal fat, the proximity and tissue similarity with the pancreas tail, may render the left adrenalectomy more difficult [8], especially in the settings of mandatory minimal glandular manipulation and compression, and forbidden cellular spillage. So, it is recommended for beginners to start laparoscopic removal of a pheochromocytoma on the right side, then the left side.

Taking into consideration that the retroperitoneal space contains the kidney, adrenal gland, and fatty tissue, it is very important to localize the adrenal gland within the surrounding fat. To avoid capsular breaking, especially in smaller-sized tumors perinephric fat containing the adrenal gland should be dissected away from the transversus abdominis muscle (laterally), the diaphragm (above), the *quadratus lumborum* muscle (posteriorly), and the pancreas or liver (medially on the left and right sides, respectively) just inside Gerota's fascia. During the separation of the perinephric fat from the diaphragm at the upper pole of the adrenal gland, the superior adrenal vessels are usually encountered and must be, carefully sealed and transected (especially in patients with large pheochromocytomas). During en bloc dissection, the perinephric fat is divided between the adrenal gland and the upper pole of the kidney using a vessel-sealing device. Next, the adrenal gland is lifted by grasping the periadrenal fat. The inferior and posterior adrenal vessels are in this way intercepted in the periglandular fat, sealed, and transected leaving the adrenal vein exposed between the gland and the inferior vena cava (right) or renal vein (left) [22]. At this moment (depending on the surgeon's experience, vessel diameter, and available surgical devices), the adrenal vein can be clipped or sealed leaving only the division of the remaining peri-adrenal fat to completion of the adrenalectomy. As a result, the adrenal gland will be removed along with its surrounding fatty tissue.

The technical feasibility of laparoscopic adrenalectomy for large pheochromocytomas in today's surgical activity is no longer a rarity [23,24]. Large right-sided tumors may be technically more challenging because of the operating space, which is limited by the liver with the inferior vena cava compressed and displaced anteriorly by the tumor, sometimes taking a lenticular shape on the medial margin of the tumor. However, large left-sided pheochromocytomas are also a source of complications. Our experience counts 23 pheochromocytomas larger than 6 cm and our intraoperative strategy is in concordance with other authors' opinions performing systemic peritumoral dissection, without manipulation of the tumoral gland, without the previous approach of the adrenal vein [25]. The purpose is to progressively free the tumor from the surrounding tissue and to take maximum advantage of gravity in achieving exposure. Another useful tool, in our experience, was the blunt 10 mm vessel seal and dividing device that helped not only achieve good hemostasis in the peritumoral fat but also protect the capsule from rupture, not mentioning also a speedy surgery timing.

Intraoperative complications

Laparoscopic adrenalectomy is considered to be the gold standard for surgery to remove the adrenal gland. Still one of the factors for intraoperative complication occurrence is pheochromocytoma along with the tumor size, surgical inexperience, patient age, and body mass index [26]. The most common intraoperative complication is hemorrhage which is in most cases possible to control in the hands of a surgeon with good laparoscopic skills and experience. Conversion to open surgery dropped from 6% in some early studies [27] to 0.6% [28]. Bleeding in a hypertensive crisis can occur from small vessels that are why special attention has to be paid to hemostasis. If proper electric hemostasis cannot be achieved and if it affects the safe dissection, applying a large gauze and pressing it into the bleeding area, was in our experience the best way to manage this situation until a clip was applied to control the bleeding. Apart from general complications during laparoscopic adrenalectomies specific aspects are related in particular to the pheochromocytoma, large tumors with important retro-caval development that compress the IVC anteriorly, present a high-risk caval injury that mandate conversion to laparotomy in most cases. Other vascular or visceral lesions can be caused by the large tumoral volume, specific to pheochromocytomas, and the need to mobilize the surrounding tissues instead of the gland, to avoid both catecholamines release or capsular breaking are the renal and the splenic veins. Major vascular injuries are recognized instantly during dissection, and it is important to evaluate the chance of controlling them laparoscopically, and not waste time converting to an open procedure [29]. Liver, pancreatic and splenic injuries are mostly due to adhesions, the presence of a large tumor or unexpected excessive tissue retraction to protect or better access the pheochromocytoma. In our experience, no solid organ injury during pheochromocytoma minimal invasive surgery forced us to convert to open surgery.

Causes of conversion

A large multicenter study showed that unplanned conversion to laparotomy during laparoscopic unilateral adrenalectomy for pheochromocytoma was independently associated with increased intraoperative hemodynamic instability episodes and postoperative complications rate [30,31]. Studies revealed that the ratio of intraoperative systolic blood pressure >200 mmHg and the total anesthesia time was an independent factor associated with conversion [32]. Although controversial intraoperative hemodynamic instability remains an important marker of the quality of pheochromocytoma manipulation during the surgery [32,33].

Another particular case of conversion in this type of tumor is represented by tumoral spillage not only due to the high risk of relapse [5,23] but also because of the high risk of undiagnosed malignancy [34], especially taking into consideration that in pheochromocytoma radiographic and histological information, including intraoperative frozen section examination, are unreliable predictors of malignancy [35,36].

However, conversion to an open procedure is warranted when laparoscopic dissection cannot be performed safely or a complete resection cannot be performed without undue trauma to the gland.

In our experience, conversion during laparoscopic adrenalectomy for pheochromocytoma was needed in 9 cases: 1 case of severe cardiac arrhythmia with cardiac arrest that required resuscitation on the operating table, 3 cases of invasive malignant pheochromocytoma, 2 cases large tumors that could not be dissected safely, and 3 cases of major vessel lesions: two inferior vena cava lacerations and one left renal vein injury.

Specimen extraction

Special care should be paid to the adrenal specimen since it might spill and contaminate the peritoneal cavity causing disease recurrence [5] or even pheochromocytomatosis [14]. This is why immediately following specimen detachment it is introduced in a retrieval bag for the following surgical steps like controlling hemostasis. Manipulation during this step should follow the dissection principles since the pheochromocytoma capsule can rupture under its weight if it is uncarefully manipulated. We recommend grasping the specimen using periglandular tissue, fascia, or vascular stumps to place it in the bag. We retrieved the bag always through the lateral incision that is enlarged accordingly to the specimen size, avoiding morcellation and contamination of the wall.

We also routinely drained the adrenal lodge, the drainage tube being exteriorized through the same incision from the specimen was retrieved. The tube stays in place for 24 hours if no bleeding is noticed.

Special attention to malignant pheochromocytoma was given to achieve an en-bloc excision of the tumor with wide surgical margins and as much peri-adrenal tissue as possible. The need to operate around the renal artery and vein or the renal hilum for achieving an en-bloc resection along with the peri-adrenal does not mandate conversion to laparotomy. However, conversion to an open procedure is warranted when laparoscopic dissection cannot be safely performed or a complete resection cannot be performed without undue trauma to the gland [5]. Hand-assisted laparoscopy is a good alternative to open conversion if a difficult dissection is encountered intraoperatively [37].

CONCLUSIONS

The best way to improve is to repeatedly follow a correct surgical pathway even from the beginning, especially when approaching a pathology with great morbidity related strictly to the delicacy and correctness of the surgical act. Experience of the high volume centers translates into excellent outcomes, achieved by minimizing complications, decreasing blood loss, and shortening hospital stays.

Abstract: *Melanoma is one of the most common types of malignancy in the world, and one known to carry a very poor prognosis until recent years. This review aims to outline the events in the history of the disease and the impact made by the discoveries along the way, as well as the modern-day consensus by referencing the updated literature regarding the present approach and future directions. In the last two decades, several studies and research have brought significant improvement in the diagnosis and clinical management of melanomas. The development of sentinel lymph node biopsy has brought major changes to the surgical approach to the disease, and modern therapies based on recently developed knowledge changed the death sentence this diagnosis once meant to a manageable condition despite its aggressiveness, keeping in mind that early diagnosis and safe margin excision remain the best and most optimistic course of treatment.*

Keywords: *melanoma, surgery, Breslow, Clark, lymphadenectomy, BRAF, immunotherapy, sentinel lymph node biopsy*

INTRODUCTION

Malignant skin tumors are among the top 10 causes of disease burden worldwide. 18.8 million new cases of cancer have been diagnosed in 2018 alone, with breast, lung, and colorectal cancer being the most frequent. It is also the second most frequent cause of death, preceded only by ischemic heart disease [1]. While skin cancer is not among the highest incidence malignancies overall, they do represent the most common malignancy in the white population. Furthermore, melanoma has had the highest increase in incidence rates – 5-fold in the past 30 years [2]. Therefore, reducing disease burden and mortality has become public health priority. Numerous studies and research have brought significant improvement in the diagnosis and clinical management of skin cancers, especially in the case of melanomas, which carried a very poor prognosis until recent years. Part of these improvements is due to the development of genetic testing for specific mutations and the subsequent development of targeted therapies. These have led to the increased survival of numerous patients and to important changes in the way this pathology is managed. Surgical excision has always held a central role in melanoma therapy, and it naturally changed and adapted along with newer treatments.

HISTORY OF MELANOMA DIAGNOSIS AND TREATMENT

The word “melanoma” originates from Greek (“melas” meaning “dark” and “oma” meaning “tumor”) and it was described for the first time in recorded history by Hippocrates in the 5th century BC. The earliest physical evidence of melanotic tumors dates from around the same time and was found in the bones of pre-Colombian mummies [3]. Throughout the following centuries, more reports of such pigmented tumors were made, though not much was understood about their origin and development. In 1806, Rene Laennec introduced the term melanosis to describe the disease as a separate entity and demonstrated the difference in its structure from other dark-colored lesions found in autopsies, such as carbon deposits in the lungs [4]. The first thorough study of the disease was made by William Norris in 1830, who followed up a patient for 3 years, described the condition clinically and the autopsy findings in detail, including the vast number of metastases, their macroscopic structure, and the hereditary character of that particular case. He was also the first one who, in later studies, highlighted a possible link between “melanosis”, and noticed a correlation between the condition and light-colored skin and hair [5]. The term “melanoma” was introduced in 1838 by Robert Carswell, who studied and described melanoma metastases, including brain localization, in detail [6]. A comprehensive analysis of primary tumors was also provided by James Paget in 1853, including the first description of the transition between a radial growth phase and a vertical growth phase [3,7].

In the 20th century, research techniques improved, and more effort was made to understand the disease and structure its treatment. In 1953, Spitz and Allen observed that nodular (or "deep") melanomas have a worse prognosis than superficial melanomas [8].

In 1954 Ackerman and Del Regato were the first to propose a staging system, comprising four groups: a – patients with the generalized disease, b – patients with clinical lymph node disease, c – patients with infra-clinical (histological) lymph node involvement, and d – patients with primary tumors. The system was based on the observation that the latter group demonstrated improved survival compared to the first group, but not much difference was observed between the two middle groups [9,10].

With time, other stage systems were developed and proposed for clinical practice, such as the one designed by McNeer and Das Gupta in 1964, which comprised three stages based on disease extension and is regarded as a precursor to the modern TNM staging system [11]. This system was expanded and improved by the MD Anderson Hospital in 1976 [12], but it still had some shortcomings, such as failing to consider the pathology of the primary lesion.

In 1969, Clark, improving earlier systems proposed by Petersen (1962)[13] and Mehnert and Heard (1965)[14], based on the microscopic aspect of the primary tumor, presented the five levels of invasion still in use today [15]. One year later, in 1970, Breslow demonstrated the importance of primary tumor thickness in overall prognosis and survival [16].

With later studies corroborating their findings, such as McGovern's for the Clark index [17] and Balch's for Breslow – which also proved that tumor thickness is more relevant for prognosis than the level of invasion [18] – these characteristics of the primary lesion were added to later staging systems. Over time, the American Joint Committee for Cancer (AJCC) and the Union Internationale Contre le Cancer (UICC) have made several attempts to establish a simple, relevant, and coherent staging system that could be applied internationally.

Following a series of proposed systems that were only partially satisfactory, and after adapting to encompass new findings, in 2002 the AJCC proposed the modern staging system, whose updated version (8th edition) is in use today [19,20]. It includes ulceration of the primary lesion as a prognosis factor, uses the Breslow index as a primary determinant of T staging, with the Clark level used only for thin tumors (<1 mm), and makes a clear distinction between clinical and pathological staging. It also takes into consideration additional prognostic factors such as age, gender, tumor location, and histological subtype.

Melanoma treatment evolved as the understanding of the disease grew. The first surgical resection of such a lesion in Western medicine was performed by John Hunter in London in 1787 [3]. By the end of the 19th century, it became clearer that surgical excision is an appropriate course of treatment, with some authors such as Herbert Snow advising adjacent lymph node resection, while William Handley suggested a 5 cm of healthy tissue around the tumor along with extensive lymph node excision [3]. This remained the standard for melanoma surgery well into the 20th century.

After Clark and Breslow's studies on the importance of primary lesion thickness in the prognosis of melanoma, surgical therapy was gradually adapted to decrease morbidity after extended excisions. A series of studies in the 1990s up to the early 2000s aimed to determine the optimal resection margin for each primary tumor stage.

Eventually, a relative consensus was established for safety margins of 0.5 cm for melanoma in situ, 1 cm for invasive melanoma <1 mm thick, and 2 cm for a Breslow index of >2 mm with some debate still ongoing about the optimal resection margin for tumors between 1 and 2 mm thick [21].

As mentioned previously, complete radical lymphadenectomy was performed as part of the surgical treatment for melanoma for most of the 20th century. The argument behind the indication was based on extensive studies on lymphatic drainage made by Rudolph Virchow and by Marie Sappey in the later part of the 19th century, and was supported and practiced by prominent surgeons like William Halsted for breast cancer in the US and, as mentioned before, by Herbert Snow for melanoma, in Britain [22].

Lymphadenectomy became an essential step in the oncological resection of various tumors for almost a century. By 1990, lymph node dissection was still performed as standard of care in melanoma treatment, whether electively (for clinically normal nodes) or therapeutically (for clinically evident lymph node involvement), but the need to find a better approach was frequently discussed, especially for small primary tumors and no clinical lymph node involvement [23].

In 1992, Morton and Cochran published a study that demonstrated the dissemination of tumor cells through lymphatic vessels first to a specific, identifiable node, called the sentinel node, then to other regional nodes [24]. They were not the first authors to use the term "sentinel node", the term had been used previously by several authors to describe the first nodes draining specific areas on the body, but based primarily on their anatomy rather than physiology [22]. Morton used the technique described by Gerota who used a blue dye to map lymphatic vessels and introduced lymphoscintigraphy for patients with axial melanoma to determine the primary draining basin [25]. Their studies were not accepted easily, but as data continued to support their findings, sentinel lymph node biopsy became an integrated part of melanoma treatment.

GENETIC MUTATIONS IN MELANOMA

It is now understood that cancers are the consequence of a series of mutations in genes that control the proliferation, differentiation, and programmed death of the affected cells. In 2002, Davies and colleagues demonstrated a significant presence of BRAF mutations in human cancers [26]. BRAF (v-RAF murine sarcoma viral oncogene homolog B1), a proto-oncogene, is a RAS-regulated serine-threonine kinase and an activator of the MAPK signaling cascade. It plays an important role in cell differentiation, proliferation, and death through extracellular signals. The mutation was found in several malignancies, including melanoma, colorectal cancer, adenocarcinomas of the lung, sarcomas, ovarian cancers, and liver cancers, and it prompted the research for other targets and pathways. Its identification in a large proportion of benign demonstrated that this mutation may be a step in melanoma development and prompted further studies [27].

Among the most frequent mutations responsible for oncogenesis in melanoma are observed in the MAPK signaling pathway (mitogen-activated protein kinase). This pathway promotes cell cycle progression, transformation, and cell survival and, in non-cancerous cells, it is activated through cytokine receptors or tyrosine kinase receptors. Ligand binding to the receptors leads to the activation of GTPase switch proteins known as RAS, which in turn activate a series of serine/threonine kinases, which ultimately activate MAPK. Permanently activated MAPK signaling has been observed in almost all melanomas [28].

BRAF is a kinase whose only known activity is in the MAPK pathway and is highly expressed in melanocytes but also hematopoietic tissue and neural cells. The most common BRAF mutation in melanoma is the V600E – a valine to glutamic acid substitution in exon 5, codon 600, a mutation that permanently activates the kinase domain [26]. These mutations are usually found in cutaneous melanoma, specifically in those tumors arising on intermittently sun-exposed skin, despite it not being a typical UV-induced DNA mutation [29].

Other mutations involved in cell proliferation are relatively rare in melanomas, such as mutations that increase RAS activity. They occur mostly in amelanotic nodular subtypes and makeup only about 10-20% of melanomas, with NRAS being the most commonly affected [30]. Interestingly, these two mutations, BRAF and NRAS seldom occur simultaneously in melanomas [31], and in the rare situations when they do, the BRAF mutation is not the typical V600E type [32], suggesting that they have overlapping oncogenic activity and either of them could activate the MAPK pathway.

The above-described mutations can also appear in benign nevi, as well as in melanomas. BRAF mutations can be found in 70-80% of dysplastic nevi [33] and NRAS in congenital nevi [34]. Given these findings, it was at first believed that the BRAF mutation was the initial oncogenic event that triggered all other changes in BRAF-positive melanoma. However, data showed that only 6% of in situ melanomas have a BRAF mutation [26], and that seems to be polyclonal (containing melanocytes with and without the BRAF mutation, or with BRAF wild type), metastatic melanoma tends to be monoclonal [35], suggesting that the mutation might occur later in the oncogenic process. Still, at any moment it occurs, BRAF activation leads to cell growth and dysregulation of the MAPK signaling pathway [36]. Other mutations or alterations can lead to the same result, like overexpression of growth factor receptors like KIT or EGFR (epidermal growth factor receptor)[37,38]. NF1 (neurofibromatosis 1, a tumor suppressor) mutations lead to melanoma proliferation through the MAPK and PI3K pathways [39].

The MTIF gene, responsible for a melanocyte-inducing transcription factor is another essential regulator of melanocyte development, survival, and function, and it can be linked to melanoma development. Its amplification can be found in 15-20% of melanomas, especially metastatic tumors, and it has been shown to contribute, alongside BRAF, to melanoma development [40].

An interesting occurrence in melanoma is the genetic heterogeneity of these tumors, both intralesional and occurring during disease progression. These findings partially explain treatment resistance, on one hand, and can influence therapeutic decisions, on the other [41]. One study investigated both benign and malignant melanocytic lesions and interestingly found that the benign lesions only showed BRAF-V600E mutations [42]. As the disease progressed, more mutations developed. In more advanced lesions, NRAS and subsequently TERT promoter mutations were found. In invasive and advanced melanomas, inactivation of CDKN2A and loss of PTEN and TP53 were observed [41,42]. All these findings suggest that the BRAF-V600E mutation may require other mutations that inhibit tumor suppressors to ultimately lead to melanoma development.

TARGETED THERAPY IN MELANOMAS

The first targeted agent for BRAF V600 was Vemurafenib, which showed significantly higher response rates than the previously used chemotherapeutic agent dacarbazine [43]. Dabrafenib was the second targeted agent to be developed, and despite some side effects such as rash, fatigue, or fever, the therapy was generally well tolerated [44]. Along with a better understanding of the BRAF gene and its interconnected activity with MEK, MEK inhibitors were developed, with trametinib being the first. Simultaneously, studies into BRAF-inhibitor resistance lead to a better understanding of the importance of MEK in the process, and the connection between the two pathways [45]. This eventually led to the association of the two agents, a BRAF inhibitor and a MEK inhibitor, which was studied in a series of clinical trials, for both dabrafenib plus trametinib, as well as for vemurafenib plus cobimetinib, with encouraging results showing a lower rate of cutaneous adverse reactions and increased progress-free survivals [46,47]. This has led to attempts to treat non-BRAF mutated melanoma with a MEK inhibitor in monotherapy, but the results were not promising, suggesting that further genetic studies into the MEK activity and its possible association with other mutations such as NRAS are necessary and could lead to new therapies [43].

Vemurafenib is a selective kinase inhibitor of the MAPK pathway in BRAF-mutated cancer cells, leading to decreased proliferation and apoptosis, while dabrafenib is a reversible, ATP-competitive BRAF inhibitor [48]. Cobimetinib is a non-ATP-competitive inhibitor of MEK1, with a high selectivity for MEK 1 over MEK2. Similarly, trametinib is an allosteric small molecule that binds preferentially to unphosphorylated MEK, preventing Raf-dependent MEK phosphorylation and activation.

In clinical practice, the RT-PCR method is widely used for BRAF mutation detection. The cobas 4800 BRAF V600 kit and the ThxID-BRAF kit have been developed together with the targeted therapeutic agents' vemurafenib and cobimetinib and dabrafenib and trametinib respectively, and are frequently used due to their accessibility, reproducibility and relatively rapid results. These tests use two different primer sets to detect the V600E mutation and the wild-type sequence and then compare the results. While this is sufficient for usual testing, other methods are available for more in-depth analysis and also for rare BRAF types (about 2% of cases), such as Sanger sequencing, pyrosequencing, and high-resolution melt analysis (HRMA)[41].

Systemic therapy for non-mutated melanoma

For decades, melanoma has been considered an incurable disease, especially in later stages, partially because both classic chemotherapy and radiation therapy are not significantly effective, with the drug Dacarbazine showing the best overall response rates of about 10-20% [49]. Research into the development of this malignancy and specific studies on metastatic melanoma has led to the discovery of genetic testing and targeted therapies on one hand, and also to the development of immunotherapies for non-mutated tumors.

There are four main types of immunotherapy: biological agents such as cytokines, interferon, and granulocyte-monocyte colony-stimulating factors; vaccination therapy; adoptive cell therapy and immune checkpoint inhibitors [50]. Biological immunotherapy such as interferons and IL2 were the first alternative to classic chemotherapeutic agents and were frequently used together, to amplify their action. Vaccination therapy is a type of specific immunotherapy that is currently studied. Oncolytic viruses are modified strains of various viruses that maintain their replication capacity but lose their virulence, and such strains have led to cell death in melanoma cell lines in vitro and animal models, by activating antitumoral immunity through the production of cytokines [51]. However, not all types of vaccination are very effective in vivo, such as DNA-based vaccines, despite proving safe and effective in laboratory settings [52]. Adoptive cell therapy is an experimental treatment alternative based on the patient's lymphocytes, which are then activated in vitro and reinjected into the patient to induce an immune response. The technique is time-consuming and elaborate, requiring specialized personnel and equipment [50]. The most effective immunotherapy studied has been the immune checkpoint inhibitors. They are designed to suppress the mechanism of self-regulation in natural immune response and target specific overexpressed molecules in the tumor they are used against. In melanoma, they target PD-1, a cell-surface molecule that downregulates B and T lymphocyte activity (Nivolumab and Pembrolizumab), or CTLA-4, a protein receptor that acts as a negative regulator of T-cell activation (Ipilimumab).

As previously mentioned, most trials for immunotherapy agents have been conducted on regionally advanced and metastatic diseases. Interferon-α has been used for over 20 years before the development of modern therapies to treat advanced disease, with moderate results, as shown in a meta-analysis by Mocellin in 2010 [54], while pegylated IFN-α demonstrated to prolong disease-free survival without improving overall survival in regionally advanced disease [55]. The treatment was associated with significant side effects varying from myalgia, fatigue, fever, headaches, and chills to depression, which could be severe and require treatment [56].

Ipilimumab has been in use since 2015. Its efficacy was demonstrated initially in unresectable metastatic melanoma and subsequently began being used as an adjuvant treatment.

Initial studies proved it increases overall survival in patients who had undergone complete lymph node resection for node metastases (overall survival at 5 years 65.4% compared to 54.4% in the placebo group) but was associated with significant adverse events (in 41.6% of patients)[57], even though these adverse reactions didn't significantly lower quality of life [58]. Ipilimumab is not currently in use as the first line of treatment in regionally advanced or metastatic melanoma.

Nivolumab was approved in 2014 and most studies compared its efficacy with Ipilimumab in the same category of patients, showing a lower rate of recurrence (recurrence-free survival at 18 months of 66.4% vs 52.7% for Ipilimumab and 70.5% vs 63.7% at 24 months) and significantly fewer adverse reactions (17.5% vs 40.4%)[57].

Pembrolizumab was approved in 2019 and showed similar results, disease-free survival of 71.4% vs 53.2% for placebo, and 14.5% moderate to severe adverse reactions vs 3.4% in the placebo group [58].

Combination therapy has proven to be more efficient than monotherapy, the association of Ipilimumab and Nivolumab led to better results in several studies(50), although toxicity may increase, with cutaneous reactions (over 50% of patients), gastrointestinal and thyroid disorders being the most frequent [56].

CURRENT RECOMMENDATIONS IN MELANOMA DIAGNOSIS AND TREATMENT

Any suspicious lesion of the skin should be carefully examined. The surrounding skin should also be checked for satellite lesions and regional lymph nodes should be palpated. Physical examination of the lesion can be completed with dermoscopy by a specialized medical professional for improved accuracy [59]. A patient's personal history of sun exposure, other skin lesions, or cancers is also important, as well as a careful history of the lesion in question. Excisional biopsy with subsequent microscopic examination of suspicious lesions is the only way to accurately establish a melanoma diagnosis. The excisional biopsy should include margins of 1-2 mm around the lesions and into the subcutaneous tissue. Other surgical methods like incisional biopsy are not recommended with very few exceptions and superficial shave biopsies should be avoided because accurate lesion thickness cannot be correctly established [60]. If suspicious palpable masses are identified around the lesion or node basin, further evaluation may be necessary, the most accessible of which is soft-tissue ultrasonography, which can be paired with a fine-needle aspiration.

Once a melanoma diagnosis has been established through biopsy, wide local excision of the scar and surrounding tissue is recommended, the margins of which are established based on Breslow thickness [61]. For in situ melanomas – 0.5 to 1.0 cm; for Breslow < 1.0 mm – 1.0 cm; for Breslow between 1.0 and 2.0 mm – 1.0 to 2.0 cm; and for Breslow > 2.0 mm – 2.0 cm margins are recommended. The histological examination should be performed on permanent sections, given that frozen sections may lead to false negative results [62]. Mohs surgery is also not recommended, with certain exceptions in very superficial tumors located in delicate anatomical sites [61]. Complex reconstruction involving skin flaps should be postponed until microscopic margins are established. Some guidelines accept covering the defect with non-adherent dressing until the final histological result is obtained [61,63].

The spread of malignant cells from the primary tumor occurs primarily through lymphatic vessels to distant sites, through regional lymph nodes. The most valuable predictors for nodal dissemination are Breslow thickness and the presence or absence of ulceration and they are the basis for the indication of a sentinel lymph node biopsy [64]. Thus, all tumors thicker than 1.0mm should be considered for lymph node biopsy. Smaller tumors should be evaluated for poor prognosis factors such as ulceration or microvascular invasion and a decision can be made on that basis [65]. Recent studies have also evaluated the role of complete lymph node dissection in the case of a positive SLN, which was the initial standard of care. They did not demonstrate improved survival and metastasis-free survival in the case of early completion of lymph node dissection, as opposed to monitoring and conducting the procedure in a delayed fashion, when the nodes become identifiable clinically or ultrasonographically [66].

Staging aims to be a simple and practical method to determine a patient's prognosis and guide treatment. It is also helpful in reporting data for future studies and clinical trials. The latest American Joint Committee for Cancer (AJCC) TNM staging system defines separate clinical and pathological staging [20,65]. Clinical staging (cTNM) is based on imaging and clinical examination and pTNM takes into account histological results obtained after surgery. Stage 0 represents melanoma in situ. Stage I is a localized disease, with IA representing tumors of less than 1 mm thickness with or without ulceration (T1a/T1b) or 1-2 mm without ulceration (T2a). Stage II melanoma is also localized, but with larger primary lesions, or ulceration. IIA denotes a 1-2 mm ulcerated lesion, IIB a >2 mm lesion with or without ulceration. Stage III is regional melanoma, with node involvement or satellite or in-transit lesions, with subtypes “a” to “d” for the extent of invasion. It is the subgroup with the most variable 5-year survival rates, ranging from 93% for IIIa to 32% for IIId [68]. Stage IV signifies generalized disease, with distant site dissemination. No subgroups were defined for this stage, given that the overall survival is similar among these patients [50].

Other prognostic factors can have an impact on prognosis. The female gender appears to be associated with a better prognosis, while melanomas of the head and neck are associated with a worse prognosis [69]. Older patients have overall higher mortality [70], nodular and amelanotic melanomas have a worse prognosis [71] while melanoma developed on pre-existing nevi are less aggressive than de novo melanoma [72].

Adjuvant therapy is essential for the outcome of stages III and IV melanoma, the stages with the highest rates of recurrence and dissemination. For earlier stages – stages I and IIA – surgical excision and follow-up seem to be the optimal treatment. For stages, IIB and IIC the risk of adverse reactions is greater than the risk of recurrence, so adjuvant treatments are generally not indicated. For stage III and IV, immunotherapy with Nivolumab or Pembrolizumab, alternatively, if BRAF-V600E genetic test is positive, Dabrafenib and Trametinib is the first-line option [73].

CONCLUSIONS AND FUTURE DIRECTIONS

Diagnosis and treatment of melanoma have evolved greatly to the benefit of patients, especially in later stages, and is even more important as the incidence of melanomas continues to rise. The development of sentinel lymph node biopsy brought major changes to the surgical approach to the disease, and the discovery of the genetic and immune basis of melanoma development changed the treatment protocols that have been used for decades. Classic chemotherapeutic agents are relatively ineffective, recently studied chemotherapy presents more promising results, nonetheless, newer agents also present side effects, sometimes leading to interrupting the treatment, such as colitis and diarrhea for immunotherapy, or keratoacanthoma and squamous-cell carcinoma for targeted therapies [56]. Experimental studies are being conducted with T-cell-based adoptive cell transfer immunotherapy, which proved effective in a laboratory setting [74]. Simultaneously, there is also a need to optimize screening. At the moment, screening and follow-up of low-risk melanomas are based on clinician-led surveillance, but there are proposals to increase patient education on self-examination [75]. Results are yet inconclusive, some studies already show that patients tend to detect melanomas when they are thicker [76], yet the value of self-examination has been proven before [77]. Modern technology is also being researched to aid early diagnosis. Gene profiling can identify low or high risk of developing melanoma [78]. Dermoscopy can be used with computer software to analyze suspicious lesions more efficiently [79]. Finally, the increasing number of smartphone apps focusing on healthcare, including dermatology, should be assessed for accuracy, as many potentially dangerous lesions can go overlooked [80-82].

In conclusion, understanding melanoma has improved spectacularly, which benefits the increasing number of new patients and the therapies developed based on this knowledge changed the death sentence this diagnosis meant until 20 years ago to a manageable condition despite its aggressiveness, keeping in mind altogether that early diagnosis and safe margin excision remain the best and most optimistic course of treatment.

Abstract: *Obesity affects the population worldwide. A hypercaloric diet associated with a sedentary life, stress, and genetic background, triggers various metabolic disorders, such as metabolic syndrome, diabetes mellitus, cancer, cardiovascular diseases, non-alcoholic fatty liver disease, and cognitive impairment. A healthy diet correlated with physical activity, not smoking, and moderate alcohol consumption reduces the risk of developing metabolic diseases. The Mediterranean diet contains antioxidants, fiber, polyunsaturated fats, and compounds with anti-inflammatory, anti-oxidant, anti-cancer, and anti-obesity properties. In a wide variety of species including humans, the reduction of calories between 20-40% significantly improves health, increases longevity, and delays the development of various pathologies. The main aim of this review is to present the comparative effects of the Mediterranean diet versus the hypercaloric diet on insulin sensitivity.*

Keywords: *obesity, diet, MetS, insulin, metaflammation*

INTRODUCTION

Currently, obesity affects the young and adult population worldwide. Hypercaloric diet, sedentary life, and stress lead to obesity [1-3]. Sugar has a well-established metabolic effect. Therefore, the direct pathway includes fructose, which induces lipid and carbohydrate metabolism dysregulation. Indirectly, an excessive sugar intake leads to body weight and fat gain, which further induces the perturbation of lipid and carbohydrate metabolism [4].

A hypercaloric diet triggers dyslipidemia, a key player in the pathogenesis of metabolic diseases [5]. Hyperinsulinemia is installed when insulin secretion is increased, insulin pulses are decreased, and/or hepatic insulin clearance is reduced [6]. This metabolic state is induced by several factors such as the modern Western diet, over-nutrition, and genetic background. Once installed, hyperinsulinemia perturbs the balance of the insulin-growth hormone (GH)-insulin-like growth factor (IGF)-axis and switches to an insulin: GH ratio, leading to lipogenesis and inhibition of lipolysis and further to obesity [6]. In mammals, GH stimulates the production of IGF [7]. The hypothalamus, the pituitary gland, and the liver regulate the GH/IGF-1 system. GH is primarily synthesized by the somatotrophs from the anterior pituitary gland, but reproductive tissues, lymphoid tissues, and the gastrointestinal tract may also syntheses it. Moreover, other endocrine axes may have permissive actions on GH and stimulate IGF-1 expression [8].

Ceramides are lipids from the sphingolipid group, which can act at the plasma membrane, endoplasmic reticulum, and mitochondria levels, being involved in insulin signaling and glucose homeostasis [9]. Under certain metabolic dysregulation (low androgen levels in males and high androgen levels in women) IGF signaling is perturbated leading to metabolic dysfunction and type 2 diabetes [10].

The most common metabolic disorders correlated with hypercaloric diets include metabolic syndrome (MetS) [11,12] diabetes mellitus type 1 and 2 [13], obesity [2,3,14], cardiovascular diseases (CVD)[15], various cancer types [16-21] infertility, non-alcoholic fatty liver disease (NAFLD) and cognitive impairment [16,22].

HYPERCALORIC DIET AND INSULIN SENSITIVITY

Clinically, insulin resistance (IR) was defined as the incapacity of insulin to increase cellular glucose uptake [23]. Several factors such as age, body weight, genetic predisposition, sedentary life, stress, overstimulation of the sympathetic nervous system, and inflammation may induce the development of IR [24]. Currently, a wide range of populations worldwide have a sedentary life, which correlated with unhealthy diets will conduce to an increased incidence of obesity development related to Diabetes mellitus type 2 [25]. Epigenetic modifications were detected: altered DNA methylation of type 2 diabetes-specific genes such as IRS1, KCNQ1, PPARG, and TCF7L2 [25].

In muscle and liver, IR is correlated with increased circulating levels of free fatty acids, and mitochondrial and endoplasmic dysfunctions [26]. It is well known that type 2 diabetes is installed as a consequence of IR, a process that is frequently associated with obesity. In obesity, hyperglycemia induces excessive insulin production that further conduces to increased beta-cell mass and at the end beta-cell apoptosis. In the last decade, obesity has been named a low-grade inflammatory state, known as metiflammation [27].

In overweight adults, a diet poor in vegetables harms gut microbiota, leading to IR [28].

The muscle, the liver, and the adipose tissue may have increased amounts of ceramide, which is further correlated with IR. The high carbohydrate diet leads to an increased serum level of triglycerides (TG) and decreased levels of HDL-cholesterol, events that are correlated with an increased risk of CVD [25]. Chronic hyperglycemia induces subclinical inflammation, which is the major factor of endothelial damage and represents the link between diabetes and CVD [29].

It is well known that overnutrition conduces to weight gain, which further creates a vicious cycle characterized by IR/hyperinsulinemia. This event will conduce to atherogenic dyslipidemia development, illustrated by hypertriglyceridemia, decreased HDL, and increased LDL [30]. IR affects 25-35 % of the Westernized population [16,22].

Metabolic syndrome (MetS) is defined as a multi-factorial disorder, which received several names such as IR syndrome, metabolic syndrome, Reaven's syndrome, Syndrome X, and the deadly quartet [12,31]. MetS are characterized by abnormal obesity, dyslipidemia, decreased levels of HDL-cholesterol, IR, and hypertension. This metabolic disorder is mainly characterized by obesity and IR. The risk of coronary heart disease and type 2 diabetes is significantly reduced by treating MetS [32].

One of the most common disorders of pregnancy is gestational diabetes mellitus (GDM), which is developed in the second and third trimesters of pregnancy, leading to hyperglycemia of various severity [22,33]. GDM development harms both mother and child, resulting in cesarean delivery, macrosomia, and neonatal hypoglycemia. Moreover, women with GDM have a huge after-pregnancy risk of CVD and type 2 diabetes development [22]. A decreased amount of vegetables and an increase in animal products may cause IR. Pre-pregnancy intake of processed and unprocessed meat is associated with an increased risk of GDM development [34].

Short-chain fatty acids (SCFAs) produced by our gut microbiota can affect the cardiometabolic phenotype because they can enter the systemic circulation and may directly affect the metabolism or the peripheral tissue function [35]. Therefore, SCFAs stimulate the sodium/glucose transporter-1 expression leading to increased absorption of monosaccharides. SCFAs directly influence the host's satiety, because they can promote the glucagon-like peptide-1 (GLP-1) and peptide YY release. This is possible after the interaction of SCFAs with G-proteins expressed by enteroendocrine cells. More than that, SCFAs promote lipogenesis and inhibit fatty acid oxidation, triggering obesity [36].

MEDITERRANEAN DIET AND INSULIN SENSITIVITY

A healthy lifestyle includes a healthy diet, physical activity, not smoking, and moderate consumption of alcohol, especially for women [37]. A vegan diet based only on the consumption of grains, vegetables, and fruits, reduces the risk of MetS, diabetes, and [28, 38], and prevents CVD [39].

A diet rich in fiber, more than 25 g/day in women and more than 38 g/day in men decreases the risk of type 2 diabetes. In addition, a diet that contains nonviscous compounds such as whole grains and insoluble cereal fibers may influence the postprandial glucose response or could be very well fermented by the colon gut microbiota [40]. The results of 30 randomized clinical trials performed on men and women, reported that the consumption of milk and dairy milk products is associated with a decreased activity of insulin and fasting insulin levels [41].

In the case of healthy subjects, an acute endurance exercise in the fasted state causes important changes: stable blood glucose amount, low blood insulin levels, increased lipolysis with an increased blood-free fatty acid concentration, maintenance of the muscular glycogen and high intramyocellular TG oxidation [42].

Recent studies illustrate that replacing the carbohydrates from the diet with fat will decrease fasting TG and will increase the HDL level. Therefore, the results of the meta-analysis that included obese patients who received a high-fat versus low-fat diet, reported after the consumption of a low-fat diet a significantly elevated level of TG and a decreased level of HDL-cholesterol [43].

The Mediterranean diet (MD) consists of antioxidants, fiber, polyunsaturated fats, and compounds with anti-antioxidant, anti-inflammatory, anti-cancer, and anti-obesity properties [44]. Fats intake, especially monounsaturated fat (MUFA) helps the body to reduce the level of insulin. Moreover, 3–4 g of MUFA will decrease the TG levels and blood pressure (BP) in subjects with MetS. Cohort studies reported that a dairy fat consumption of 50% saturated fat leads to a decreased incidence of MetS [43]. A Mediterranean-style diet has positive effects in reducing the MetS prevalence and cardiovascular complications [45]. Even World Health Organisation (WHO) recommends a diet poor in carbohydrates, for adults and children. Their consumption reduces circulating insulin levels and decreases body weight and TG levels [46]. On the other hand, the decreased level of circulating insulin conduces to an increased level of circulating fatty acids, utilized for oxidation and further ketone bodies synthesis. However, this diet has negative effects on the human body in long term [46].

Willems AEM and his research team, published 2021 the results of a meta-analysis regarding the impact of low-carbohydrate and low-fat consumption on markers of MetS in obese patients without cardiometabolic disease [47]. The studies reported that weight loss is the most efficient way to reduce fasting glucose levels independent of macronutrient intake. Moreover, the specific studies reported that carbohydrate and fat intake, but without changing the percentage in the intake of these macronutrients, improved diastolic blood pressure (DPB) and circulating TG levels, without any effect on weight loss [47]. The IR was also improved with both diets, while HDL was only improved in the low-carbohydrate diet. This study concluded that the reduction of carbohydrate and fat intake are not the only factors that improve the MetS markers. This suggests that the guidelines for the prevention of MetS must be re-evaluated [47].

Cellular studies reported that the consumption of polyphenols, such as green tea catechins and epigallocatechin gallates, resveratrol, and curcumin reduce TG accumulation, and stimulate lipolysis and fatty acid-beta oxidation, leading to the reduction of obesity-related inflammation [48].

Ros E and his research team, observe the long-term effects of the MD without any energy restriction on CVD patients [49]. The study reported that MD had good effects on oxidative stress, atherosclerosis, blood pressure, lipids, and inflammation. The consumption of high-unsaturated fat and antioxidant-rich diets such as the MD one may prevent CVD development [49]. Therefore, olive oil, red wine, and nuts have beneficial effects on human health [50]. Dietary polyphenols including fruits, vegetables, whole grains, coffee, tea, and nuts, influence glycemia and type 2 diabetes, by promoting the tissue's glucose uptake, and therefore improving insulin sensitivity [51].

Ryan MC and co-workers conducted a randomized study that included twelve non-diabetic NAFLD patients (6 females/6 males) across 6 weeks. The study participants received MD, rich in MUFA. The study conclusions indicated that MD reduces liver steatosis and improves insulin sensitivity [52]. Abenavoli L and colleagues obtained similar results in NAFLD patients who consumed MD [53].

The clinical study Coronary Diet Intervention conducted by Delgado-Lista J, which enrolled 1,002 coronary patients from Spain, compare the effects of MD rich in virgin oil versus the low-fat diet on the impact of cardiovascular events. At the beginning of the study, 70.6% of the patients had LDL-cholesterol <100 mg/dL, 56.3% of them were obese, 64.4% were former smokers and only 9.6% were active smokers. However, between patients who received MD and a low-fat diet, no difference regarding weight, hypertension, fasting plasma glucose, or lipid profile was observed [54].

The preliminary results of the ongoing trial conducted by Sayón-Orea C regarding the effects of MD and physical activity on 6874 men and women (aged 55 to 75 years) with MetS and no CVD history enrolled between September 2013 and December 2016, illustrated a significant change. The change was visible in BMI, body weight, waist circumference, and lipid profile after 12 months compared with the control group [55].

The scientific group of Papadaki reported changes in 18 of 28 MetS components and risk factors [body weight, BMI, waist circumference, SBP, DBP, glucose, insulin, homeostatic model assessment of insulin resistance (HOMA-IR) index, total cholesterol, LDL-cholesterol, HDL-cholesterol, TG, alanine transaminase, hepatic fat mass, C-reactive protein, interleukin-6, tumor necrosis factor-a, and flow-mediated dilatation] and lower risk of CVD incidence, after the consumption of MD [56]. Moreover, low-caloric MD and exercise training are important targets in the treatment of

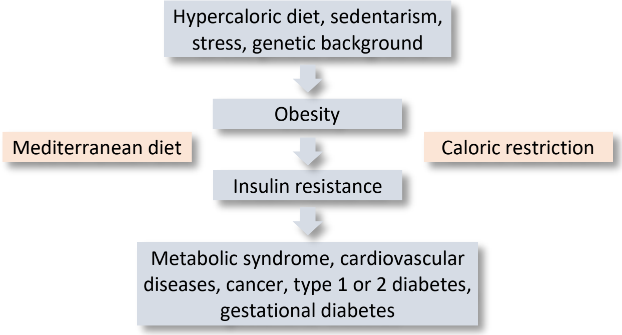
NAFLD [57].

CALORIC RESTRICTION (CR)

CR represents the reduction of kilocalorie (kcal) intakes between 20 - 40%. Therefore, food restriction has been demonstrated to improve health and increase longevity in various groups of species, including humans, dogs, nematodes, rodents, rotifers, and non-human primates. Moreover, CR may delay the development of various pathologies such as autoimmune diseases, CVD, cancer, diabetes, renal diseases, neurodegenerative diseases, and respiratory diseases [58].

The term intermittent fasting (IF) refers to extended periods (16-48 hours) in which people eat little or nothing, alternating with periods of normal food intake. Moreover, periodic fasting (PF) means the periods of fasting or fasting-mimicking performed between 2 to 21 days or more. Studies performed on experimental models (mice and rats) summited on IF and PF, reported a decreased incidence of age-related disorders such as diabetes, CVD, cancer, and neurological disorders [59]. Therefore, a 60% energy restriction 2 days per week, and a five-day diet of 750-1100 kcal for normal and overweight patients conduces to weight loss and improves IR, and reduces the risk of CVD. Thus, IF improves health and counteracts diseases by the activation of several pathways involved in adaptive cellular response, mitochondrial death, autophagy, and DNA repair [59]. Taking into account all the aspects presented, the inflammation generated by obesity can be a key element for the development of oral pathologies such as periodontal disease [60-63]. Depression-related obesity is very dangerous, which may conduce to antidepressants consumptions [64,65].

Figure 1: The relationship between obesity-inducible factors, the Mediterranean diet, caloric restriction, and various metabolic pathologies



Hypercaloric diet, sedentarism, stress, genetic background
Obesity
Mediterranean diet
Caloric restriction
Insulin resistance
Metabolic syndrome, cardiovascular diseases, cancer, type 1 or 2 diabetes, gestational diabetes

CONCLUSIONS

IR is a consequence of many factors such as body weight, stress, genetic predisposition, inflammation, and over-stimulation of the sympathetic nervous system. Hypercaloric diets lead to obesity and IR, pathologies associated with MetS installation, and further CVD development. Healthy diets such as the MD, in combination with weight loss, especially for individuals who are overweight or obese, can drastically improve the cardiometabolic risk factors. MD reduces the level of TG and stimulates lipolysis and fatty acid-beta oxidation. CR, IF and PF improve general health and may delay the development of age-related disorders.

Abstract: *Diabetic foot is one of the main long-term complications of diabetes, having a significant impact on a patient's quality of life. However, prevention by daily checking of the limbs and observance of the rules of care remains particularly important to avoid total or partial amputation. This paper aims to highlight the main challenges and progress in the treatment of the diabetic foot. To achieve this, we analyzed a database consisting of more than 100 articles published in recent years, approaching the treatment of the diabetic foot. The main problems that occur with the diabetic foot are peripheral vascular disease and diabetic neuropathy. These can lead to blisters and skin lesions that can eventually lead to ulcers in the lower limbs and even amputation. In conclusion, prevention is the main method of treatment for diabetic foot, followed by the treatment of each complication depending on when it is identified and its severity.*

Keywords: *diabetic foot; treatment of diabetic ulcers, diabetic foot*

INTRODUCTION

Diabetic foot is one of the most common complications of diabetes, being the leading cause in the world of lower limb amputation [1], as well as frequent hospitalizations in patients with diabetes [2,3]. According to the World Health Organization, diabetic foot syndrome is defined as "ulceration of the foot (distally from the ankle and including the ankle) associated with neuropathy and different grades of ischemia and infection" [4]. The main factors involved in the pathogenesis of diabetic foot ulcers are neuropathy and peripheral vascular disease [5]. However, other factors intervene in the occurrence of diabetes complications such as poor control of blood sugar and blood pressure, dyslipidemia, obesity, smoking, old age, inadequate prevention strategies, and long-term diabetes [5,6]. Considering that there are some limitations of specific treatment, attention remains focused on prevention and foot care education [4]. Careful management of the diabetic foot, which requires a good doctor-patient relationship, is a sure way to prevent amputation and maintain body integrity. Focusing on educating the patient can lead to a better understanding of his pathology, being a very important step in preventing the complications of the disease [5,7]. On the other hand, initiating the most appropriate treatment of complications depending on the stage at which they are discovered is essential in the healing process and even to prevent a possible amputation [3,6,8].

MATERIALS AND METHODS

This review aims to highlight the progress of treatment methods and best strategies providing a quick and correct diagnosis, as well as the complications of the diabetic foot.

We have selected 100 studies in English, German, and Romanian that presented information on methods of treating diabetic foot, difficulties encountered in the differential diagnosis and treatment of diabetic foot, as well as the complications of diabetic foot. Articles presenting the pathophysiology of the diabetic foot were also excluded.

Databases such as PubMed, Up-to-date, Medline, and NCBI were used to perform the search using keywords such as diabetic foot, diabetic foot complications, diabetic foot treatment, differential diagnosis of diabetic foot, and advances in diabetic foot treatment. To select the papers, exclusion criteria were imposed, such as the article publication date should not exceed 20 years old, and the publications to be in English, German, and Romanian treatment protocols were also analyzed.

RESULTS

Diagnostic and differential diagnosis of diabetic neuropathy

Diabetic neuropathy is one of the most common complications of diabetes, with about 50% of patients with type 1 or type 2 diabetes showing symptoms specific to diabetic neuropathy including pain, numbness, tingling, weakness, and difficulties with balance [9]. The most prevalent of diabetic neuropathies is generalized, symmetrical polyneuropathy, in which case may occur sensitive, motor, and autonomic manifestations [10,11].

There is also a high percentage of asymptomatic diabetic peripheral neuropathies, so recognition and prompt intervention are extremely important and reduce the risk of an insensitive foot injury, as well as a possible amputation [8]. Diabetic neuropathy is a diagnosis of exclusion, which is why other possible etiologies must be excluded, given that neuropathy in diabetic patients may have other causes (Table 1) [12]. In addition, some diabetics may have several causes of neuropathy at the same time [10]. The Rochester Diabetic Neuropathy Study reported that nondiabetic peripheral neuropathies were present in about 10% of patients [13].

Table 1: Different diagnoses of diabetic neuropathies [12]

Metabolic disease	Thyroid disease (common) Renal disease
Systemic disease	Systemic vasculities Nonsystemic vasculities Paraproteinemia Amyloidosis
Infectious	HIV, VHB, Lyme
Inflammatory	Chronic inflammatory demyelinating polyradiculoneuropathy
Nutritional	Deficit of B12, post-gastroplasty Pyridoxine, Thiamine, Tocopherol
Industrial agents, drugs, and metal	Industrial agents: Acrylamide, Organophosphorous agents Drugs: Alcohol, Amiodarone, Colchicine, Dapsone, Vinka alkaloids, Platinum, Taxol Metals: Arsenic, Mercury
Hereditary	Hereditary motor, sensory, and autonomic neuropathies

Thus, to optimize outcomes and lead to specific treatment in the diabetic patient, rapid recognition and proper management are essential.

Treatment

When we talk about a diabetic foot, we inevitably think of infection, hospital admission, amputation, and emotional and financial impact [14]. To achieve the best results for a diabetic patient it is necessary to implement a good prevention strategy [15,16]. As we all know, prevention is not always easy, especially for older patients with other comorbidities, but it is essential for a better prognostic and good quality of life [15,17]. The prevention of diabetic neuropathy is based on two goals: good glycemic control and a balanced lifestyle [7,12].

The patient's education is extremely important, in this process it is necessary to present his pathology, the complications that may occur along the way, and simple techniques to follow, such as checking and daily care of the feet, wearing special shoes, signaling any new foot mark and avoiding foot trauma [14,18]. The management of diabetic foot requires a rapid intervention in front of any type of wound, if possible by a multidisciplinary team [16,19]. Daily diabetic foot screening is the best prevention [7,20].

Numerous advances have been made in the management of diabetic foot in recent years, many of which have been applied especially in clinics dedicated to diabetic foot care [14,18]. Most important in the management of diabetic foot is a multidisciplinary team consisting of specialists to act quickly in the face of any type of wound [16,19].

To determine the best treatment method, it is important to determine the severity of the diabetic foot [18]. The treatment can be conservative or surgical [21]. As long as conservative treatment is chosen, it can be performed in an outpatient setting as long as the patient is compliant, the ulceration is superficial and there are no signs of systemic damage [20]. Also, during the treatment period, it is very important to maintain the glycemic values within normal limits and to respect the nutritional regime and the daily exercise program [16,22].

The first step in treating foot ulcer is inspection, to stabilize the degree of damage and the existence or not of the infection, then the wound is cleaned, and if necessary local anesthesia can be performed (many patients have polyneuropathy and no anesthesia is needed) to debridement [23]. In the case of superficial ulcers, a multidisciplinary approach is important to prevent evolution (Table 2) [22].

There is currently a modern local treatment method that involves the use of hydro active dressings, which promote healing through cell proliferation processes in a humid environment. This is done to prevent infection and/or reduce the microbial load, prevent necrosis or eliminate existing ones and adapt to each stage of the wound healing process (cleaning, granulation, and epithelialization) [24].

Table 2: Treatment for superficial uncomplicated foot ulcers [22]

Active ulceration Peripheral neuropathy +/- PAD	Clinic evaluation	Patients evaluation	Core	Adjuncts
Non-limb threatening Ulcer	- Superficial - Minimal to no cellulitis - No bone or joint involvement - No significant ischemia - No toxicity	- Reliable - Will conform to treatment - Good support system - Evaluation of comorbidities	- Offloading - Debridement, Dressing - Management of infections - Vascular evaluation if needed - Foot-sparing surgery	- Control blood sugar - Treat comorbidities - Nutrition - Control edema - Physical and emotional therapy
Limb threatening ulcer	Check both feet and legs, and compare Before any intervention, the ulcer probes deeply Note location May involve bone or joint Cellulitis >2cm Lymphangitis, gas, crepitation Ischemia +/-foot pulses, Doppler Systemic toxicity, temperature, white blood cell, lymph nodes Escher, *callor*, granulation tissues	- Unreliable - Poor support systems - Poor control of comorbidities	Therapy - Admit to hospital – complete bed rest - Employ core and adjunct - control blood- stabilize comorbidities - Especially consult (cardiology, renal, infectious disease, etc) - Empirical broad-spectrum antibiotics – adjust by culture and sensitivity - Labs and X-ray Early vascular evaluation and Rx after control of infarction - Foot-sparing surgical vs amputation/revisions - Close follow up	
Septic ulcer	- Same as for limb-threatening ulcer - Be sure to check for undermining deep tissue exposure, abscess, bone, and gas	- Same as limb-threatening ulceration	- Immediate admission – complete bed rest – protect wound and foot, esp heel - Employ core and adjuncts - Intravenous broad-spectrum antibiotics/fluid replacement and resuscitation - Labs and X-rays - Culture and sensitivity – blood culture - Control edema - Emergency aggressive surgical debridement - control all activity infarction, including possible amputations - Stabilizing medically – blood glucose, cardiac(MI, CHF) renal, esp consult (cardiology, renal, ID, etc.) - Evaluate later for antihypertensive, beta-blockers, calcium channel blockers, ACE inhibitors - Early vascular evaluation and Rx after control of infarction - Close follow up	

If the foot ulcer is infected it is especially important to determine if there is a systemic or only local infection [25]. The signs of local infection are erythema, edema, suppuration, and unpleasant odor, but often if the patient has kidney failure they do not show [26].

Depending on the degree of damage and the level of infection, the method of treatment is decided, but the basis of any method of treatment is the initiation of antibiotic therapy and wound care [25].

To choose the best antibiotic therapy, the following criteria are taken into account:

- Local bacterial resistance pattern,
- Proper antibiotic history,
- Gram stains of deep exudate,
- Appearance of wound and pus,
- Associated co-morbid conditions like renal, hepatic, and cardiac impairment [22]

DISCUSSIONS

Clinical aspects and the pathophysiology of diabetic foot

Because there are multiple etiologies underlying this concept, the diabetic foot is considered to be a "syndrome" [27]. It is one of the most common complications of diabetes which in the long-term, if not treated properly, can lead to amputations, disability, and reduced quality of life [4,28]. It is well known that around 25% of diabetic patients will develop a foot ulcer in their lives [28,29]. The pathophysiology of a diabetic foot ulcer is based on triad neuropathy, trauma with secondary infection, and arterial occlusive disease, which appears in various forms [17].

Due to the nerve damage, there is a loss of pain and thermal sensitivity that makes the feet vulnerable to minor injuries caused by excessive pressure, and mechanical or thermal damage [30,31]. Furthermore, motor neuropathy leads to intrinsic muscle atrophy, and foot deformities by altering the biomechanics of the foot, as well as limited joint mobility and postural and coordination deviation [32]. In the end, the formation of calluses comes as an expression of the plantar excessive pressure [28].

One of the goals of treating any ulcer with neuropathy is to reduce weight, regardless of the presence of ischemia [6,33]. Last, the effects of the onset of autonomic neuropathy are diminished sweating, altered blood flow regulation, and microvascular dysfunction, which will lead to dry skin and cracks [21,34]. Repetitive trauma and impaired proprioceptive and exteroceptive sensitivity predispose to skin injury leading to atrophy and dislocation of plantar fat, followed by ulceration and infection [28,35].

There are situations in which, inattention to certain signs (redness, blister formation) or lack of routine foot care, leads to the formation of ulcers and the appearance of infections, undesirable things in diabetic patients with neuropathy, or a history of foot ulcers [3]. Studies have shown that the risk of ulceration increases in diabetic patients with neuropathy, a history of amputations, or foot deformity [16,17].

There are advantages and disadvantages to each kind of wound treatment and multiple solutions for wound dressing are present (Miculickz pomade, 1% silver sulfadiazine cream, zinc hyaluronate solution, bovine collagen, hyperbaric oxygen therapy, hydrocolloid dressing or synthetic skin substitutes)[15,16]. Most of them need real confirmation in randomized studies.

Adjuvant care of diabetic foot ulcers implies systemic factors control of hyperglycemia, control of infection, treatment of vasculopathy (sulodexide, cilostazol) or local factors-peripheral neuropathies, control of pressure at foot level (custom-made ortheses and shoes)[36].

Charcot neuro-osteoarthropathy

Charcot neuro-osteoarthropathy or the Charcot Foot is one of the most severe complications of diabetes [37]. The main factors that lead to this disease are a combination of neuropathy, repeated microtrauma caused by increased weight, and an abnormal bone metabolism leading to inflammatory reactions [35,38]. The result is the destruction of the normal architecture of the foot, subluxation, dislocation, and deformity, most commonly in the ankle and foot [39]. Charcot's Foot is an urgent condition, often associated with ulcers and osteomyelitis, and requires proper management by a foot specialist [40].

Osteomyelitis

Osteomyelitis represents a severe infection involving bone, which occurs due to non-healing ulcers, and if not treated properly may lead to major amputation [27,28]. Two-thirds of the patients with diabetic ulcers may be affected by osteomyelitis, so this complication requires increased attention [38].

In addition, patients with a diabetic ulcers may develop osteomyelitis without any signs of pain, but there may also be a decrease in local signs of infection caused by neuropathy and peripheral arterial disease [41].

CONCLUSIONS

Diabetes mellitus is a chronic disease, characterized by high blood glucose levels [42].

The long-term complications of diabetes are vascular and neurological, and of these, diabetic foot syndrome is one of the most serious consequences in terms of the health complications it generates and the impact on quality of life. It includes ulceration, infection, and osteoarthropathy, known as Charcot's foot. Proper prevention and care of the feet are essential for the early identification of problems and mitigation of consequences. This includes patient education, prophylactic skin, nail care, and proper footwear.

Depending on the severity of the condition, the best method of treatment for the diabetic foot is decided. There are several options, both invasive and non-invasive, for treating this disease.

Abstract: *According to the results of the conducted study there were distinguished the peculiarities of perception of the image of a junior officer by servicemen who participated in hostilities and had various PTSD symptoms. The study included 233 male servicemen with combat experience. The age of the participants varied from 20 to 55 years. It was determined that the image perception of the direct commander by the servicemen who did not have any PTSD symptoms had been influenced by both the key features of the modern way of fighting and the way a protective mechanism of consciousness acted, which gave the possibility to maintain mental health under combat conditions. These servicemen considered the awareness, kindness, and physical strength of their commander to be not important. The first stage was occupied by his/her ability to adequately fulfill his/her leadership function and the power of his/her spirit – the courage and love of the Motherland, which formed his/her reliability. Servicemen who had PTSD symptoms were less satisfied with the role of a junior officer and considered him/her to be less capable of meeting their expectations. They were less interested in commanders who could involve them in situations that required quick, brave action and complete responsibility for the entrusted part of common affairs. The most important factors in the structure of the direct commander image in both studied groups were the power of personality (the ability of self-regulation); however, the servicemen with PTSD symptoms had a specific orientation of these factors – to help their subordinates. They were quite selfishly aimed at using their direct commanders as a way of getting help.*

Keywords: *leader, serviceman, service and combat activity, combat experience, post-traumatic stress disorder, psychological recover*

INTRODUCTION

It was quite difficult to overestimate the role of a junior officer who was a direct commander during the fight. He/she shared with his/her subordinates all the complexities of the service, informed them about orders of senior officers, implemented the coordination of actions of small military groups, made relevant decisions related to the life of the unit, and resolved conflict situations in the team [1]. The behavior of warlords had a deep effect on the mental health of those whom they had to lead [2]. According to Tedeschi and Mcnally, the perception of their leaders influenced not only the way they responded to stressful events, such as hostilities, but also an individual's desire to apply for psychological help in times of personal crisis [3].

The implementation of combat tasks and the preservation of the lives of entrusted him/her servicemen fully depended on the competence of the direct commander’s actions under combat conditions. According to Baran and Scott to make a unit’s actions effective the subordinates had to trust in the actions of their commander, trust that he would not pose them to the actions with unjustified risk [4]. The research conducted by Sweeney determined that leaders who showed competence before combat actions had a higher level of trust among their subordinates, while those who demonstrated a lack of competence and a lack of previous combat experience could feel distrust from the side of their subordinates [5]. Fisher, et al. [6] received similar conclusions to Sweeney [5] and proposed to add that successful leadership under combat conditions was possible due to previous successes on the battlefield. According to them the experience of participation in hostilities strengthened the leader's confidence and formed appropriate beliefs about self-efficacy.

The experience of joint actions on the battlefield imposed a significant imprint on the perception of the direct commander by his/her subordinates. In particular, the studies conducted by Xue, et al. [7] and Ramchand, et al. [8] proved that servicemen’s perception of their commander (leader) directly related to post-traumatic stress disorder. Other conducted studies (Castro and McGurk; Du Preez, Sundin, Wessely, and Fear; Iversen, Fear, Ehlers, et al.; Jones, Seddon, Fear, et al.; McGurk, Sinclair, Thomas, et al.) also figured out that the perception of the leader by servicemen on the battlefield related to the fair and equal attitude, praise, interest, and concern [9-13]. However, in general, the studies lacked theoretical explanations of the relations which could help to make the image of leadership the only factor that could be changed. The only exception was the study by McGurk, et al. [13] who used the theory of resources conservation that was proposed by Hobfll as an explanation of how positively and negatively leaders could contribute to obtaining or losing the resources, which could explain the connection with PTSD [14].

However, the experienced stressful events could interfere with the acquired combat experience as well as the features and qualities which the serviceman realized in him/herself, his/her comrades, and the commander overcoming life challenges. The negative experience caused by the mental traumatization was painful (Kolesnichenko), having the desire to weaken its power a serviceman could want both to find help and to find the perpetrators [15]. He/she could become isolated, believing that people around him/her could not understand and help. The inability of the serviceman to accept his/her combat experience (Kalesnichenko) [16], and loss of his/her mental health (Kolesnichenko) [17] could have a negative influence on the interaction within the unit, on the perception of the image and the role of the commander (Jansen and Delahaij) [18]. Although the military hierarchy regulated the relations between the leaders and subordinates, unofficially servicemen could abandon their leaders. Such refusal, according to Pierro, Cicero, and Bonaiuto, et al., could cause floats and counterproductive behavior within the military teams [19].

METHOD

Participants and Procedure

The study was conducted in 2022, it was a part of another bigger study related to the determination of important qualities of military leaders. The study included 252 servicemen (42.16% of them were mobilized; 57.84% of them were servicemen under the contract) who participated in hostilities. All the participants were divided following the scale “Mississippi Scale for Combat-Related PTSD” into two groups – group A included the servicemen (155 people) whose PTSD symptoms did not exceed the norm (up to 78 points); group B included the servicemen (97 people) whose indicators exceeded the norm (more than 78 points). This study was based on the presence of definite PTSD symptoms of servicemen who, on request, received qualified individual consulting help from military psychologists and participated in group works aimed at restoring their resilience ability as well as at increasing their ability to accept their own combat experience. It was not about the formed PTSD.

All procedures carried out in the study conformed to the ethical standards of the 1964 Helsinki Declaration and its later amendments. All participants gave consent for their data to be used in this research.

Instruments and Measures

To identify the peculiarities of perception of the ideal representation (image) of a junior officer by the servicemen who participated in hostilities and had PTSD symptoms based on the analysis of modern and foreign studies there were distinguished more than 50 descriptions of the characteristics of military leaders. After the first stage of the Delphi estimation method, where the experts were selected from the military leaders with different ranks, subordinates including those with considerable combat experience, military instructors, and lecturers from the higher military educational establishments. The total number of experts was 65 people. There were made up separate lists of 30 characteristics to evaluate the sergeants, junior and senior officers. It had to be highlighted that the descriptions of the leader’s characteristics in the lists were significantly reduced and edited due to the experts’ recommendations. Due to that definite list of 30 characteristics, which was formed to evaluate the junior officer by the 11-point scale (from 0 to 10 points), the participants who took part in hostilities were asked to evaluate the importance of those characteristics in the "ideal" junior officer, according to their point of view.

To evaluate the degree of PTSD expressiveness of the servicemen who participated in the study there was used "Mississippi Scale for Combat-Related PTSD" [20]. Nowadays, it was one of the most common methods used to measure the signs of PTSD. The scale included 35 statements, each of which can be estimated on a five-point scale. The total indicator which was made up of this method gave the possibility to estimate the degree of influence of the traumatic experience transferred by an individual.

Data Analysis

To represent the data, there was used the main descriptive statistics (arithmetic mean M and standard deviation SD). To compare the estimates provided in the selected groups there was used the T-criteria of the Student. Moreover, there was used the procedure of factor analysis by Principal Components to distinguish the structure of the image of the junior officer due to the given points. Mathematical data was processed with the help of SPSS 17.0.

RESULTS

The points given to the selected groups of servicemen who participated in hostilities were proposed by 30 qualities used to make the perfect image of a junior officer. The points were compared with the help of the T-criterion of the Student. This information was presented in Table 1.

According to Table 1, due to all 30 characteristics which were used to describe the ideal junior officer, the service-men without PTSD symptoms had much higher indicators than the servicemen of the second group. The data indicated not only the presence of different ideas of the representatives of these groups concerning the ideal of a junior commander but also the more negative attitude of the group representatives with PTSD symptoms towards a junior commander in general and towards the role he performed.

It should be noted that both groups had differences between the most important quality and the least important which were minimal. Thus, in the first group, the most important was considered the ability to “adequately informed the subordinates concerning the commanders' orders, pointing out their importance, and could ensure their implementation" (9.16 ± 1.51), and the least important was “own achievements, professionalism and character traits made him/her an attractive model to follow” (8.50 ± 1.97).

In the group with PTSD symptoms, the most important characteristic was "a patriot, who proved by his/her actions his/her love of the Motherland and the ability to protect it" (8.58 ± 1.90), and the least important, as in the first group, was "own achievements, professionalism and character traits made him/her an attractive model to follow” (7.60 ± 2.54). Thus, despite the different evaluation tactics in these groups, the least important were both It should be noted that both groups had differences between the most important quality and the least important which were minimal. Thus, in the first group, the most important was considered the ability to “adequately informed the subordinates concerning the commanders' orders, pointing out their importance, and could ensure their implementation" (9.16 ± 1.51), and the least important was “own achievements, professionalism and character traits made him/her an attractive model to follow” (8.50 ± 1.97).

In the group with PTSD symptoms, the most important characteristic was "a patriot, who proved by his/her actions his/her love of the Motherland and the ability to protect it" (8.58 ± 1.90), and the least important, as in the first group, was "own achievements, professionalism and character traits made him/her an attractive model to follow” (7.60 ± 2.54). Thus, despite the different evaluation tactics in these groups, the least important were both the status and exemplarity of the commander (his/her achievements).

However, if the first group put in the first place a specific function of the leader – the ability to adequately perform the role of intermediate (between the senior commander and subordinates) leader, which ensured the coordination of small units’ actions, the second group valued his/her civil position and his/her own choice – love of the Motherland and the ability to concentrate all strength to protect it; it seemed that only that could justify all the sufferings which they had survived with their commander, under his/her direct guidance.

A lower quantity of points could indicate less satisfaction with the role of junior officers, and their inability to meet expectations. It was necessary to point out that the commander's patriotism was highly appreciated by the representatives of the first group in which he/she, conditionally, occupied the second stage. However, it could be assumed that the servicemen of the first group reflected the protective mechanism on the estimation of the direct commander.

The protective mechanism ensured the preservation of their mental health – the focus on the process of performing their functions under combat conditions – hence occurred a specific view of the role of the commander.

To clarify the assumptions which were made, there occurred a need to look more precisely at the most and the least important qualities of junior officers in both groups. It was inappropriate to consider in detail the whole hierarchy of the characteristics of a junior officer in the distinguished groups due to the minimal differences in the estimations of the most and the least important qualities.

Table 1: The Characteristics of the ideal image of a junior officer in the groups of servicemen with different PTSD signs (in standard points)

№	Variable	Studied		$t_{кр}$	p
		group A	group B		
1	He/she worried about the welfare of his/her subordinates and found opportunities to organize the most convenient conditions for their service in the current circumstances	9.02±1.77	8.14±2.43	3.09	.01
2	He/she was brave and strong-willed, and with his/her example he/she inspired the subordinates to overcome difficulties	9.08±1.54	8.14±2.49	3.33	.01
3	He/she was able to take any situation under his/her control, to make up-to-date decisions	9.03±1.68	8.24±2.44	2.79	.01
4	He/she was reliable, did not give up, and acted effectively even having minimal resources	8.96±1.67	8.10±2.31	3.16	.01
5	He/she saw the prospects that his/her unit had and could unite the subordinates to achieve these prospects	9.01±1.63	8.06±2.46	3.36	.01
6	His/her achievements, professionalism, and character traits made him/her an attractive model to follow	8.50±1.97	7.60±2.54	2.96	.01
7	He/she adequately informed the subordinates concerning the commanders' orders, pointing out their importance, and could ensure their implementation	9.16±1.51	8.31±2.34	3.17	.01
8	He/she had good communication skills and could adequately resolve conflict situations	9.04±1.62	8.46±2.23	2.21	.05
9	He/she could explain, teach, and help to form the necessary skills as well as the traits of character	8.92±1.67	8.00±2.34	3.34	.001
10	He/she was aware, well-informed, and could easily acquire the necessary knowledge as well as professional experience	8.84±1.76	7.91±2.39	3.31	.001
11	He/she could form the team – everyone in the unit was "in his/her place" both due to professional skills as well as due to personal traits, which ensured his/her effective work	9.05±1.62	8.03±2.37	3.72	.001
12	He/she formed confidence in the better future that which individual wanted to follow with his/her brethren	8.83±1.62	8.00±2.22	3.15	.01
13	He/she was confident in him/herself, in his/her decisions, and in the unit itself – he/she did not allow any doubts, uncertainty, and apathy which could undermine the efficiency of the unit activity	9.01±1.61	8.13±2.26	3.33	.001
14	He/she adequately evaluated the importance of solving certain problems. To solve them he/she showed the appropriateness of persistence, honesty, and stubbornness	9.04±1.52	8.25±2.06	3.25	.01
15	He/she was quite independent – made up-to-date decisions and took responsibility for the given orders	8.95±1.78	7.90±2.33	3.82	.001
16	He/she was friendly and available for the subordinates to communicate, they could share their problems as well as their doubts. He/she was also available for their families who were concerned about the lives of their loved ones	8.82±1.78	8.22±2.13	2.30	.05
17	He/she was emotionally balanced and stress-resistant and could control his/her negative experience	8.97±1.62	8.29±1.96	2.84	.01
18	His/her morality, belief perseverance, and ability to defend those beliefs gave him/her the possibility to be a role model for his/her subordinates	8.89±1.60	8.17±2.08	2.92	.01
19	He/she was demanding to others as well as to him/herself and inspired the others to imitate him/her by own self-discipline	8.98±1.47	8.10±2.23	3.42	.001
20	He/she was tactful being demanding to his/her subordinates and taking care of them. He/she represented respect and maintained a sense of dignity in his/her subordinates	8.91±1.66	8.16±2.17	2.91	.01
21	He/she was able to quickly and adequately evaluate the professional situation and its changes, to make necessary decisions for the normalization of the situation	9.08±1.51	8.17±2.29	3.48	.001
22	He/she formed the feeling of "we" in servicemen: "We are defenders", "If not we, then who?"	9.03±1.64	8.22±2.30	2.99	.01
23	He/she carefully considered his/her decisions, calculated all the possible complications within the process of their implementation	8.98±1.69	8.23±2.16	2.90	.01
24	He/she formulated his/her opinion, gave consistent orders, and agreed with other executives	9.05±1.49	8.42±2.06	2.63	.01
25	He/she maintained good physical form, could bear the hardness of work on par with everybody in the unit if it was necessary, he/she could take on the professional functions of any of the subordinates	8.76±1.77	8.27±2.15	1.87	.1
26	He/she could take on full responsibility for the actions of his/her subordinates	8.96±1.68	8.29±2.26	2.51	.05
27	He/she ensured the information security of his/her unit, did not allow the leakage of information related to the servicemen and their families	9.05±1.64	8.50±1.97	2.29	.05
28	He/she was a patriot, who proved by his/her actions his/her love of the Motherland and the ability to protect it	9.12±1.77	8.58±1.90	2.22	.05

29	He/she could adequately evaluate the physical and psychological state of his/her subordinates, could organize the necessary help for them	9.11±1.50	8.40±2.09	2.92	.01
30	He/she was professional – had good professional knowledge, skills, and experience in their implementation under combat conditions	9.05±1.70	8.44±2.20	2.33	.05

There was a need to highlight that such minimality of differences of estimations of the most and the least important characteristics of the direct commander in both studied groups of the participants in hostilities testified the syncretic (fusion) of the perception of his/her image, as a significant individual in the life of a serviceman, while surviving under combat conditions directly depended on him/her.

In the first group, the most important (those who occupied leading positions and ranks in the hierarchy) were the following qualities:

1) adequately informed the subordinates concerning the commanders' orders, pointing out their importance, and could ensure their implementation (9.16 ± 1.51);

2) a patriot, who proved by his/her actions his/her love of the Motherland and the ability to protect it (9.12 ± 1.77);

3) could adequately evaluate the physical and psychological state of his/her subordinates, could organize the necessary help for them (9.11 ± 1.50);

4) able to quickly and adequately evaluate the professional situation and its changes, to make necessary decisions for the normalization of the situation (9.08 ± 1.51);

5) brave and strong-willed, with his/her example he/she inspired the subordinates to overcome difficulties (9.08 ± 1.54).

Conditionally the least important in the first group (those who occupied the least leading positions and ranks in the hierarchy) were the following qualities:

1) own achievements, professionalism, and character traits made him/her an attractive model to follow (8.50 ± 1.97);

2) maintained good physical form, could bear the hardness of work on par with everybody in the unit, if it was necessary, he/she could take on the professional functions of any of the subordinates (8.76 ± 1.77);

3) friendly and available for the subordinates to communicate, they could share their problems as well as their doubts. He/she was also available for their families who were concerned about the lives of their loved ones (8.82 ± 1.78);

4) formed confidence in the better future that which individual wanted to follow with his/her brethren (8.83 ± 1.62);

5) aware, well-informed, and could easily acquire necessary knowledge as well as professional experience (8.84 ± 1.76).

As could be seen, it was not so important for servicemen, who retained their mental health throughout the fight, which achievements their direct commander had, and whether he was well-informed, friendly, and strong. Among all the personal traits, only his/her patriotism and courage were important. For these servicemen, the first place was occupied by his/her ability to adequately fulfill his/her leadership functions – to set the combat tasks with adequate consideration of the combat situation and the subordinates he/she had.

In the group that had PTSD symptoms, the following characteristics received the highest points:

1) a patriot, who proved by his/her actions his/her love of the Motherland and the ability to protect it (8.58 ± 1.90);

2) ensured the information security of his/her unit, did not allow the leakage of information related to the servicemen and their families (8.50 ± 1.97);

3) had good communication skills and could adequately resolve conflict situations (8.46 ± 2.23);

4) professional – had good professional knowledge, skills, and experience in their implementation under combat conditions (8.44 ± 2.20);

5) formulated his/her opinion, gave consistent orders, and agreed with other executives (8.42 ± 2.06).

The participants of hostilities who had PTSD symptoms considered the following characteristics to be the least important for junior officers:

1) own achievements, professionalism, and character traits made him/her an attractive model to follow (7.60 ± 2.54);

2) quite independent – made up-to-date decisions and took responsibility for the given orders (7.90 ± 2.33);

3) aware, well-informed and could easily acquire necessary knowledge as well as professional experience (7.91 ± 2.39);

4) could explain, teach, and help to form the necessary skills as well as the traits of character (8.00 ± 2.34);

5) formed confidence in the better future that which individual wanted to follow with his/her brethren (8.00 ± 2.22).

For the servicemen of the second group as well as for the first one the achievements of their commander and his/her awareness were not important. Moreover, they did not believe that he/she could bring them to a better future, or help them to overcome their problems related to their personal life (to form the necessary traits). It seemed that those psychologically injured servicemen transferred to the image of the direct commander their confidence that their lives had no prospects, and no one could help them (one of the PTSD signs) neither due to their initiative (due to the love to their relatives) nor due to their functional responsibilities.

However, among the most important characteristics of the direct commander, three out of five in their formulation in one way or another indicated their ability to protect their subordinates. The other two were related to the cognitive functions which, among other things, were able to ensure the definite success of servicemen who, due to the loss of mental health, had problems with attention and order understanding. Thus, the attitude towards the direct commander by the servicemen who had PTSD symptoms showed opposite tendencies – on the one hand, they sought protection and help to keep the success in performing the given tasks and not lose the remains of self-esteem, on the other hand – they did not believe the fact that their direct commanders themselves or by the order of senior officers could help them to cope with their negative experience, and could direct them to the path leading to the "better future." The negativity of their estimations related to junior officers was caused by internal contradictions concerning their attitude towards them, the attitude which combined the search for protection and helping with the despair in the fact that they could help them (such PTSD characteristics as the belief in the uniqueness of their traumatic experience and the unpromising life).

Moreover, there were several characteristics in the process of their estimation in two groups, there had been distinguished the highest differences (more than 10 positions/ranks).

Thus, the servicemen whose PTSD symptoms did not exceed the norm, higher positions were occupied with the following characteristics:

- able to quickly and adequately evaluate the professional situation and its changes, to make necessary decisions for the normalization of the situation (4th position in contrast to 16.5th position in the second group);

- brave and strong-willed, with his/her example he/she inspired the subordinates to overcome difficulties (5th position in contrast to 19th position in the second group);

- could form the team – everyone in the unit was "in his/her place" both due to professional skills as well as due to personal traits, which ensured his/her effective work (7.5th position in contrast to the 25th position in the second group).

Instead, in the second group, higher positions were occupied with the following characteristics:

- could take on full responsibility for the actions of his/her subordinates (8.5th position in contrast to 20.5th in the first group);

- emotionally balanced and stress-resistant, and could control his/her negative experience (8.5th position in contrast to 19th in the first group);

- maintained good physical form, could bear the hardness of work on par with everybody in the unit, if it was necessary, he/she could take on the professional functions of any of the subordinates (10th position in contrast to 29th in the first group);

- friendly and available for the subordinates to communicate, they could share their problems as well as their doubts. He/she was also available for their families who were concerned about the lives of their loved ones (14th position in contrast to 28th in the first group).

This data could indicate that servicemen with PTSD symptoms were less interested in commanders who could involve them in situations that required quick, brave actions, and complete responsibility for the entrusted part of the common affairs; instead, they required a commander who could take on the responsibility for their failures as well as a part of their direct responsibilities, and at the same time he/she would not condemn (express any negative attitude).

There was a need to consider the structure of characteristics of junior officers formed with the help of a factor analysis due to the estimations made by the servicemen from the selected groups.

In the group of servicemen, where the indicators of PTSD symptoms did not exceed the norm, after the simplification procedure, there was formed a three-factors structure (see Table 2), described 78.47% of the symptoms' dispersion. This structure was presented in Table 2.

The content of the first and the most important factor (40.56%) was determined with the following variables "emotionally balanced and stress-resistant, and could control his/her negative experience" (0.815), "able to quickly and adequately evaluate the professional situation and its changes, to make necessary decisions for the normalization of the situation"(0.771), "maintained good physical form, could bear the hardness of work on par with everybody in the unit, if it was necessary, he/she could take on the professional functions of any of the subordinates"(0.771), "confident in him/herself, in his/her decisions and in the unit itself – he/she did not allow any doubts, uncertainty, and the apathy which could undermine the efficiency of the unit activity"(0.743), and "demanding to others as well as to him/herself, and inspired the others to imitate him/her by own self-discipline" (0.663). This factor was interpreted as the power of "I" and as the power of personality based on a developed ability to self-regulation.

The second factor (23.05%) was determined by the variables such as "had good communication skills and could adequately resolve conflict situations" (0.796) and "adequately informed the subordinates concerning the commanders' orders, pointing out their importance, and could ensure their implementation" (0.781). This factor could be marked as professional communicative competence, which showed up, both in the ability to formulate a combat mission and convey information as well as in the ability to resolve the conflict.

Table 2: The structure of the characteristics of junior officers formed following the estimations made by servicemen who did not have clearly expressed signs of PTSD (in standard points).

Variable	Factors		
	1	2	3
He/she adequately informed the subordinates concerning the commanders' orders, pointing out their importance, and could ensure their implementation	0.275	0.781	0.235
He/she had good communication skills and could adequately resolve conflict situations	0.343	0.796	0.208
He/she was confident in him/herself, in his/her decisions, and in the unit itself – he/she did not allow any doubts, uncertainty, and apathy which could undermine the efficiency of the unit activity	0.743	0.273	0.435
He/she was emotionally balanced and stress-resistant and could control his/her negative experience	0.815	0.359	0.139
He/she was demanding to others as well as to him/herself and inspired the others to imitate him/her by own self-discipline	0.663	0.234	0.291
He/she was able to quickly and adequately evaluate the professional situation and its changes, to make necessary decisions for the normalization of the situation	0.794	0.342	0.186
He/she maintained good physical form, could bear the hardness of work on par with everybody in the unit if it was necessary, he/she could take on the professional functions of any of the subordinates	0.771	0.259	0.302
He/she was professional – had good professional knowledge, skills, and experience in their implementation under combat condition	0.413	0.397	0.819

The third factor was completely correlated with the variable "was professional – had good professional knowledge, skills, and experience in their implementation under combat conditions" (0,819). Some clarifications of the content of this factor were made by a variable "was confident in him/herself, in his/her decisions and in the unit itself – he/she did not allow any doubts, uncertainty, and apathy which could undermine the efficiency of the unit activity" (0.435), which emphasized the active energetic position of the servicemen who had professional knowledge and experience. Accordingly, this factor was marked as professional efficiency – the ability to act effectively based on professional knowledge and experience.

For the servicemen who had expressed PTSD symptoms, the structure of the characteristics of junior officers was simpler and had only 2 factors, which described 79.88% of the signs' dispersion. This structure was presented in Table 3.

The content of the first factor (59.55%) was defined with the following variables "clearly saw the prospects that his/her unit had and could unite the subordinates to achieve these prospects" (0.887), "was brave and strong-willed, with his/her personal example he/she inspired the subordinates to overcome difficulties"(0.877), "was reliable, did not give up, acted effectively even having minimal resources" (0.859), "was professional – had good professional knowledge, skills, and experience in their implementation under combat conditions" (0.844), "adequately evaluated the importance of solving certain problems. To solve them he/she showed the appropriateness of persistence, honesty, and stubbornness" (0.837), "own achievements, professionalism and character traits made him/her an attractive model to follow" (0.832), "was able to take any situation under his/her control, to make up-to-date decisions"(0.827), "was confident in him/herself, in his/her decisions and in the unit itself – he/she did not allow any doubts, uncertainty, and apathy which could undermine the efficiency of the unit activity" (0.815), "adequately brings to subordinates leadership, their importance, capable of ensuring their implementation adequately informed the subordinates concerning the commanders' orders, pointing out their importance, and could ensure their implementation" (0.805), and "worried about the welfare of his/her subordinates and found opportunities to organize the most convenient conditions for their service in the current circumstances" (0.761). This factor had a weight that exceeded the weight of the second factor and combined the variables, the vast majority of which described the ability of a junior officer to self-regulation, but unlike the situation in the first group, this variable received a specific direction – to ensure a prospective development and well-being of their subordinates.

The second factor (20.33%) was determined by two variables – "was friendly and available for the subordinates to communicate, they could share their problems as well as their doubts. He/she was also available for their families who were concerned about the lives of their loved ones" (0.885) and "was emotionally balanced and stress-resistant, and could control his/her negative experience" (0.847). Those were the variables that occupied much higher positions (ranks) in servicemen with the signs of PTSD than in the servicemen of the first group which were already marked as a tendency not to condemn their subordinates but to help them.

Table 3: The structure of the characteristics of junior officers was formed following the estimations made by servicemen who had expressed PTSD symptoms (in standard points).

Variables	Factors	
	1	2
He/she worried about the welfare of his/her subordinates and found opportunities to organize the most convenient conditions for their service in the current circumstances	0.761	0.363
He/she was brave and strong-willed, and with his/her example he/she inspired the subordinates to overcome difficulties	0.877	0.238
He/she was able to take any situation under his/her control, to make up-to-date decisions	0.827	0.296
He/she was reliable, did not give up, and acted effectively even having minimal resources	0.859	0.209
He/she saw the prospects that his/her unit had and could unite the subordinates to achieve these prospects	0.887	0.254
His/her achievements, professionalism, and character traits made him/her an attractive model to follow	0.832	0.332
He/she adequately informed the subordinates concerning the commanders' orders, pointing out their importance, and could ensure their implementation	0.805	0.305
He/she was confident in him/herself, in his/her decisions, and in the unit itself – he/she did not allow any doubts, uncertainty, and apathy which could undermine the efficiency of the unit activity	0.815	0.369
He/she adequately evaluated the importance of solving certain problems. To solve them he/she showed the appropriateness of persistence, honesty, and stubbornness	0.837	0.360
He/she was friendly and available for the subordinates to communicate, they could share their problems as well as their doubts. He/she was also available for their families who were concerned about the lives of their loved ones	0.272	0.885
He/she was emotionally balanced and stress-resistant and could control his/her negative experience	0.310	0.847
He/she was professional – had good professional knowledge, skills, and experience in their implementation under combat conditions	0.844	0.294

As it could be seen, the structure of the characteristics of a junior officer within the servicemen who had the expressed PTSD symptoms had some similarity with the structure given by the first group, it also referred to the power of personality (ability to self-regulation) and definite communicative competence; however, the mentioned factors had a specific orientation in this group – to help his/her subordinates. They were quite selfishly aimed at the use of their direct commanders to help them, their structure "omitted" professional efficiency, achievement of professionally important goals, and so on.

DISCUSSIONS

Although the study conducted by Sheerin C.M., et al. [21] which used a more abstract research plan did not reveal any connections between PTSD and negative attitude towards the world in general, the study was conducted gave the possibility to suggest that having expressed PTSD symptoms the people around were perceived more negatively (at least those who were responsible for the lives of a serviceman – their direct commanders).

In the study by Bartholomew, et al. it was determined that servicemen who had signs of PTSD were less focused on their future [22]. In particular, the servicemen who had the signs of PTSD had disbelief in the achievement of a better future which extended to others, to those who had to direct the achievements of this better future to the whole team – to the direct commander.

It was interesting that real and perceived social support, as a factor that affected stress overcoming, had been already studied earlier, for example, it was discussed in works by Smith, Benight, and Cieslak [23]. An interesting phenomenon was identified in the study which was related to internal conflict attitude towards an individual the one who had to help, who was responsible for that morally and formally – that individual was a direct commander. He was perceived both as the one whom they expected to get help from and as the one whose real ability to help they had poorly trusted.

Caska-Wallace et al. worked with the negative changes in servicemen who were under PTSD influence [24]. They determined that the increase in problems in relationships between veterans and their partners referred to effective communication as well as communication related to the address of problems' solutions. The results of the conducted research suggested that not only a partner, but also a commander, and probably another significant person who surrounded a serviceman with PTSD symptoms, was taken as one who had to help, to solve the problems of psychologically traumatized servicemen, however, he/she could not solve those problems. That became a reason for the conflicting attitude of the serviceman towards definite surroundings.

Moreover, it had to be noted that if this study of an individual, who did not have signs of PTSD in the structure of the commander image, distinguished his/her strong personality and the ability to self-regulation as leading factors, the research by Rahman, et al. figured out that the perception of self-efficacy was a kind of traumatic stress prevention [25]. Conducting a certain analogy, it could be assumed (even if that required further studies) that the perception of the figure of the commander, as self-effective and capable of self-regulation was a kind of prevention of PTSD formation in his/her subordinates in the future. The procedure of study did not give any possibility to suggest whether the perception of the commander as an effective one was the prevention of PTSD symptoms in subordinates, or whether the absence of signs of PTSD reduced the negativity in the perception of the commander's figure, of his/her self-efficacy, of his/her "I", or of the experience became a reason for the posttraumatic growth and perception of oneself and of the one who ran the process of overcoming the life troubles, as those which had a significant individual power (Tedeschi and Calhoun) [26]. Also, the format of the study did not give the possibility to reveal whether the presence of PTSD symptoms caused the situation that servicemen were less interested in the commander who could involve them in dangerous swift-fleeting conditions, or whether servicemen who avoided danger lost their opportunities for productivity and growth following the study by Jamieson, et al. [27].

Unfortunately, the study did not give any possibility to identify cause-effect relationships, it did not give the possibility to determine whether PTSD symptoms had an influence on the image of the military leader, or whether the attitude towards the commander became one of the reasons for acquiring PTSD symptoms during the fight. Thus, the determination of those relationships would be the purpose of the feather studies.

CONCLUSIONS

Thus, the conducted study showed that the existing extreme experience of participating in hostilities led to the syncretic perception of the image of the junior commander – all qualities were perceived as extremely important.

In servicemen who did not have signs of PTSD (able to accept their combat experience as well as experience of interaction under combat conditions), the perception of the direct commander image had been influenced both by the peculiarities of the modern way of battle conduction (the actions made by small groups which were coordinated by the leader – that was where significant importance of the ability to adequately inform about the leaders' orders and to implement the role of a coordinator came from) and by the action of a protective mechanism of consciousness, which gave the possibility to maintain mental health under combat conditions, so-called focus on the process of performing their combat tasks.

For these servicemen, the awareness, kindness, and physical strength of their commander were less important. His/her ability to adequately fulfill his/her leadership function (pose combat tasks with adequate consideration of the combat situation and his/her subordinate forces) and the power of his/her spirit including the courage and love of the Motherland, which formed his/her reliability (gave the possibility to perform the combat tasks under extreme conditions and not to give those tasks up).

The servicemen with expressed PTSD symptoms were less satisfied with the role of a junior officer. They considered him/her less capable of meeting their expectations. They were less interested in commanders who could involve them in situations that required quick, brave action and complete responsibility for the entrusted part of the common affair, they required more the commander who would take care of them. Moreover, that commander would not blame the subordinates for their failures, but also, he/she would take on a part of their professional duties and responsibilities for their activity and inactivity.

In the servicemen with expressed PTSD symptoms the negativism of the attitude towards the role of the direct commander was caused by internal contradictions – on the one hand, they looked for the commander who could protect and help, on the other hand – they did not believe that he/she could help them, considering their experience to be unique, which was not appropriate for knowledge and experience of overcoming others.

In the structure of the direct commander image in both studied groups the most important factor was the power of personality (ability to self-regulation), however, in the servicemen with the expressed PTSD symptoms, these factors had specific orientation – to help their subordinates. They were quite selfishly aimed at using their direct commanders to help them.

REVIEW

The Role of Vitamin D in the Development and Progression of Osteoarthritis

Symeon Naoum[1]

[1] 251 General Air Force Hospital, Orthopedic Department, Athens, Greece; naoumsimeon@gmail.com

Correspondence: Symeon Naoum, naoumsimeon@gmail.com

Abstract: *Low levels of vitamin D in patients with osteoarthritis (OA) rather adversely affect the structure and function of articular cartilage. Low levels of vitamin D are also associated with joint pain, limited physical activity, quality of life, as well as decreased muscle strength, primarily in the lower extremities with adverse OA progression. A high percentage of low vitamin D levels was found in patients with OA and joint arthroplasty as well as a less satisfactory postoperative follow-up in patients with low vitamin D levels. The administration of vitamin D supplementation in patients with knee osteoarthritis has been associated with improved articular cartilage architecture, and reduced joint pain, combined with improved functionality and quality of life in patients with OA.*

Keywords: *arthroplasty; vitamin D; osteoarthritis; vitamin D supplementation; vitamin D receptors*

INTRODUCTION

Osteoarthritis (OA) is defined as a heterogeneous group of conditions, leading to symptoms and signs associated with a disorder of joint cartilage, as well as with lesions of the subchondral bone and joint boundaries [1-3]. It is distinguished into primary OA when it cannot be attributed to a distinct pathological disease and secondary OA when it is related to other conditions such as injury, congenital bone disease, metabolic diseases, crystal deposition disease, or neuropathic arthropathy (Charcot's joint) [4-6]. In this review, we will only deal with the primary OA.

Regarding the role of vitamin D in OA development and progression, we will deal with the following important fields based on information from the PubMed database we searched for using the keywords osteoarthritis, vitamin D, vitamin D receptor, vitamin D supplement, joint replacement, until October 30, 2019:

1. Correlation of OA development with genetic polymorphisms of vitamin D receptor.
2. Effect of vitamin D on the structure and function of articular cartilage.
3. Correlation of low levels of vitamin D with the risk of OA development and progression.
4. Effect of vitamin D on OA clinical manifestations.
5. Correlation of vitamin D levels with muscle strength in patients with OA.
6. Correlation of vitamin D levels with the risk of arthroplasty and postoperative progress of OA patients' joints.
7. The role of vitamin D supplementation in patients with OA.

Before referring to the above, it should be noted that desired levels of vitamin D [as estimated by measuring the levels of 25-hydroxyvitamin D [25(OH)D] are >30 ng/mL. Levels <10 ng/mL mean insufficiency, while 10-30 ng/mL consist of a level lower than the considered optimal amount of vitamin D. In 2011 the Institute of Medicine (IOM) defined as insufficiency when the of 25(OH)D level was <20 ng/mL [7], while the Endocrine Society (ES) when the levels were at 20-29 ng/mL [8].

It should also be noted that vitamin D has a significant effect on the immune system function, as it inhibits the synthesis and action of prostaglandins, activates monocytes and macrophages, and has an inhibitory effect on the maturation and function of antigen-presenting progenitor cells and production of inflammatory cytokines such as interleukin-1 (IL-1), interleukin-6 (IL-6) and interleukin-8 (IL-8), etc [9-13]. Vitamin D deficiency in individuals with a genetic predisposition may affect the immune system's response and tolerance process by affecting T lymphocytes and B lymphocyte function [12,13].

CORRELATION OF OA DEVELOPMENT WITH GENETIC POLYMORPHISMS OF VITAMIN D RECEPTOR

The possible correlation between gene polymorphisms that encode the synthesis of the vitamin D receptor (VDR) and the risk of developing OA has been studied. However, the conclusions of those studies are contradictory. In a meta-analysis, it was reported that the active metabolite of vitamin D, 1,25(OH)2D3 binds to its receptors in the articular cartilage and may lead to hypertrophy and impairment of chondrocyte function [14]. A study found an association between the risk of OA of the hand extremities with polymorphisms of the vitamin D receptor [15], while another study in postmenopausal women with OA of the knee, it was found a correlation between this risk and a TaqI polymorphism of vitamin D receptor [16]. On the other hand, in another meta-analysis of 10 studies, no association was found between TaqI, BsmI, and ApaI polymorphisms and the risk of developing OA in the knees, hips, hands, and lumbar spine [17]. In the meta-analysis of Z.-H. Zhu et al., a weak association of ApaI polymorphism with the risk of developing OA in Asian (but not in European) patients with OA were found [18]. No correlation between vitamin D receptor polymorphisms and the risk of developing OA in the knees was found in the meta-analysis of Rodriguez-Fontenla et al. in 9 Genome-wide studies [19] as well as in other studies [20,21]. Another interesting study carried out by Hansen AK et al. found that 25(OH)D3 and 1,25(OH)2D3 led to an increase of chondrocytes proliferation, in combination with a reduction of proteoglycans synthesis, and thus with a reduction of the intercellular substance [22].

EFFECT OF VITAMIN D ON ARTICULAR CARTILAGE STRUCTURE AND FUNCTION

In male Sprague-Dawley rats, Pascual-Garrido et al. used Micro-CT analysis to detect adverse effects of vitamin D deficiency on articular cartilage. Of particular importance is Jiang X et al.’s study in rats, in which it was found that vitamin D promotes function, the differentiation of the bone marrow-derived mesenchymal stem cells (BMSCs) in mature chondrocytes, enhanced by the action of transforming growth factor-β1 (TGF-β1) and their migration to the articular cartilage [24].

Low levels of vitamin D in OA patients have been shown to adversely affect the structure and function of articular cartilage. In a study in which patients with knee OA participated, low levels of vitamin D were found to be associated with loss of knee articular cartilage as assessed by the decreased joint space [odds ratio-OR=2.3 (Cl, 0.9-5.5)] and the increased size of the osteophytes [OR=3.1 (Cl, 1,3-7,5)] [25]. Ding et al. randomly selected patients (aged 51-79 years, 50% women) in whom the volume of articular cartilage, the presence of articular cartilage deficits in knees using X-rays and magnetic resonance imaging (MRI), as well as the 25(OH)D levels, were assessed at the beginning. 2.9 years later in 353 of these individuals, a correlation between low levels of 25(OH)D and articular cartilage loss was found [26].

In a study in 2014, 80 patients were classified according to 25(OH)D levels into three groups (<10, 10-20, and ≥20 ng/mL). It was found that vitamin D deficiency (<10 ng/mL) may significantly affect the articular cartilage thickness of the peripheral part of the femur (lateral femoral condyle of the right knee and the medial femoral condyle of the left knee) as found by ultrasound [27].

Moreover, in Zheng S et al. study of 340 patients with knee OA, the results showed a correlation between low levels of 25(OH)D with the decreased knee articular cartilage volume, as well as the presence of articular cartilage deficits, bone marrow damage and an increase of synovial membrane thickness (a finding compatible with inflammation) as assessed by MRI [28].

Lastly, in another study of 340 patients with symptomatic OA of the knee and vitamin D deficiency, 25(OH)D levels were measured at the start of the study as well as 3 and 24 months later. It was found that patients with stable normal levels of vitamin D compared to patients with low levels (25(OH)D >50 nmol/L vs ≤50 nmol/L) had a lower loss of joint cartilage volume, thinner synovial membrane and less articular fluid collection [28].

Low levels of vitamin D have also been linked to increased levels of cytokines involved in inflammation in patients with OA. A study by Askari A et al. in 131 patients with OA who compared 262 healthy controls found that lower vitamin D levels were associated with higher levels of interleukin 17A (IL-17A) and interleukin 23 (IL-23), cytokines that promote inflammation in patients with OA [29].

CORRELATION OF VITAMIN D LOW LEVELS WITH THE RISK OF OA DEVELOPMENT AND PROGRESSION

Several studies have focused on the possibility and to what extent low levels of vitamin D in OA patients are associated compared to individuals of the same sex and similar age in the general population and OA progression, with the results being controversial. In Bergink AP et al. meta-analysis, no significant correlation was found between vitamin D levels [25(OH)D] and the frequency as well as the evolution of knee, hip or hand OA. In 3 cross-sectional studies, however, there was found a correlation between the low levels of 25(OH)D and the stenosis of knee joint space (OR=1.52, 95% CI:1.15-2.01). The meta-analysis of the above-mentioned three studies did not show a significant correlation between the low levels of

25(OH)D and the evolution of knee OA (OR=1.37, 95% CI:0.97-1.92). However, when only patients with progressive knee OA development were assessed, an increased risk was found in patients with low levels of 25(OH)D (OR=2.40, 95% CI:1.22-4.72) [30]. In a study of 149 patients (133 women, mean age 63.6 years) with knee OA, the vitamin D deficiency rate [25(OH)D<10 ng/mL] was estimated at 90% [31]. Chaganti RK et al. conducted a study in 1104 elderly men who participated in the "Osteoporotic Fractures in Men Study", measuring 25(OH)D levels at the beginning of the study and performing a radiographic hip examination 4.6 years later. It was found that higher levels of 25(OH)D at the beginning of the study were associated with a lower risk for 25[OH]D decrease, while men with vitamin D deficiency compared to men with normal vitamin D levels had a significantly higher risk (OR=2.19, 95% CI: 1.21-3.97) of developing hip OA [32]. Zhang FF et al. in 418 patients with clinical and radiographic knee OA found a correlation between low 25(OH)D levels and the risk of developing OA radiographically as assessed by evaluating the joint space stenosis (<15 μg/L compared to ≥15μg/L) [33,34]. On the other hand, Lane NE et al. radiographically attended the hips of 237 individuals (with an interval of 8 years) and found no correlation between levels of 25(OH)D and serum 1.25(OH)2D and OA risk progression (development of osteophytes and/or reduction of the joint space) [35]. In addition, Bergink AP et al., in 1248 elderly people (728 women and 520 men) who participated in the prospective study (Rotterdam Study) assessed the development and progression of OA knee radiographically (average follow-up time 6.5 years), found no correlation between 25(OH)D levels (at the beginning of the study) and the risk of subsequent knee OA [36]. In a cross-sectional study of 99 patients (90 women and 9 men, aged 36-80 years) with clinical and radiographic knee OA, no correlation of low 25(OH)D levels with clinical and radiographic OA severity was found [37].

EFFECT OF VITAMIN D ON CLINICAL MANIFESTATIONS OF OA

Some studies have found a correlation between low serum vitamin D levels in patients with OA and joint pain as well as limited physical activity, and quality of life, while some other studies did not. In Zheng S et al.'s study, in 340 patients with OA knees, a correlation of low levels of 25(OH)D was found with severe limitation of the patient's functionality [28]. Levinger P et al. in a study of 24 patients (68.6 ± 6.2 years) with clinical symptoms of knee OA, found a correlation between low levels of 25(OH)D (deficiency ≤50 nmol/L) and knee pain and restriction of patients' functionality [38]. In another study of 100 patients with knee OA, it was found that the vitamin D deficiency group had more severe knee pain, more severe physical limitations, a more intense feeling of fatigue, and a worse quality of life [39].

On the other hand, Lee A et al. evaluated 3824 people aged >65 years (Korean National Health and Nutrition Examination Survey) and found that the levels of 25(OH) D were not related to knee pain [40]. Also in another study of 149 patients (133 women, mean age 63.6 years) with knee OA, no correlation was found between low levels of 25(OH)D and knee pain [31].

CORRELATION OF VITAMIN D LEVELS WITH MUSCLE STRENGTH IN PATIENTS WITH OA

Of particular clinical importance is the association between vitamin D levels and muscle strength (primarily of the lower extremities muscles such as quadriceps that support the weight-bearing joints) of patients with OA (primarily knee OA). A study found that normal levels of vitamin K and vitamin D were associated with better lower extremity function [41]. Javadian Y et al. found a positive correlation between 25(OH)D levels and quadriceps muscle strength in 92 patients with knee OA knee (≥40 years old) (r=0.304, r=9.24%, p=0.005). For every increase of 25(OH)D levels by 1 ng/mL, the strength of the quadriceps increased by 14.2%±3.5% (p=0.014) [42]. In a 24 patients study (68.6 ± 6.2 years) with OA knee clinical signs, a correlation between low 25(OH)D levels (deficiency in ≤50 nmol/L) and the reduction of quadriceps muscle strength was found [39].

However, the effect of other factors, such as body mass index, should be also assessed. In a cross-sectional study of 319 patients with knee OA, a significant correlation between serum levels 25(OH)D and strength of the upper tibial muscles were found, which, however, ceased to be observed when the effect of the body mass index was estimated [43].

CORRELATION BETWEEN VITAMIN D LEVELS AND THE POSSIBILITY OF AN UNDERGOING ARTHROPLASTY IN PATIENTS WITH OA

Numerous researchers have investigated whether vitamin D levels in patients with OA are associated with the possibility of undergoing arthroplasty (mainly hip and/or knee arthroplasty) as well as their postoperative follow-up. A high percentage of low vitamin D levels was found as well as less satisfactory follow-up in patients with low levels. In a recent literature review (12 studies, 2593 patients) the percentage of patients with OA who underwent hip or knee arthroplasty with hypovitaminosis D was estimated at 47% (34.02% -59.9%) [44]. In another study, in 164 patients with hip or knee OA who were to undergo arthroplasty, vitamin D deficiency was found in 81.7%, especially in men [45]. Elevated vitamin D levels are likely to reduce the risk of OA patients undergoing total hip arthroplasty. Hussain SM et al. studied 9135 patients ≥40 years old, who participated in the Australian Diabetes, Obesity and Lifestyle Study, in which the levels of 25(OH)D during 1999-

2000, as well as the percentage of hip arthroplasty in 2002-2011, was estimated (Australian Orthopedic Association National Joint Replacement Registry). 201 patients with OA (90 men and 111 women) underwent hip arthroplasty. In men for any one-standard-deviation increase in levels of 25(OH)D, the probability of undergoing the operation was reduced by 25% (HR=1.25 and 95% CI 1.02-1.56) but not found in women (HR=1.10 and 95% CI 0.87-1.39) [46].

Regarding the effect of low vitamin D levels in patients with OA who have undergone arthroplasty, it appears that they are associated with less satisfactory postoperative results. In Zhang H et al.'s review, it was found that patients with OA who underwent hip or knee arthroplasty, and hypovitaminosis D adversely affected the postoperative results of these patients (Harris Hip Score score was higher in these patients compared to patients with normal vitamin D levels) [44]. In a study conducted in 2010, 62 patients who underwent total hip arthroplasty were compared with 62 patients of the same sex and similar age from the control group, it was found that the patients with vitamin D deficiency had less satisfactory postoperative follow-up results (p=0,038) as well as they had the lowest preoperative Harris Hip Scores (Mann-Whitney test, p=0.018) [47]. Maniar RN et al. also studied 120 patients with OA who underwent total knee arthroplasty [53.3% had preoperative levels 25(OH)D<30 ng/mL]and they assessed their functional ability before and 3 months after surgery. Before surgery, in patients with vitamin D deficiency, their functional ability was limited [Western Ontario and McMaster Osteoarthritis Index (WOMAC), p=0.040]. After surgery, in patients who received vitamin D supplementation, their functional ability was restored, which was similar to the functional ability of patients with normal vitamin D levels [48]. On the other hand, in the study of Visser E et al. in 87 patients with OA who underwent total hip arthroplasty, no correlation was found between levels of vitamin D and restoration of hip function. However, an increase in levels of 25(OH)D was observed six months after surgery, which was associated with an improved hip function (Pearson's r =-0.471, p=0.018) [49].

Regarding the dosage of postoperative vitamin D administration in patients with OA who underwent arthroplasty, there are interesting results from a randomized, double-blind 24-month study of Bischoff-Ferrari et al. in which participated 273 patients underwent knee arthroplasty. 137 patients received 2000 IU of vitamin D while 136 patients received 800 IU per os daily. Even though the administration of 2000 IU was accompanied by a significant increase in 25(OH)D levels (45.6 ng/mL vs 37.1 ng/mL of the 800 IU dose after 24 months, p <0.0001). No difference regarding the restoration of operated knee function, nor on the radiographic progression of the other knee OA, between the group of patients who were administered 2000 IU and 800 IU respectively (30,5% vs 31,3%, p=0.88) [50].

THE ROLE OF VITAMIN D SUPPLEMENTATION IN PATIENTS WITH OA

Animal studies have shown that vitamin D has a protective effect on the articular cartilage architecture [51,52]. In an animal study, micro swings that were on a diet rich in cholesterol, it was found that vitamin D had a protective effect on the architecture of articular cartilage (reduction of inflammation and fat infiltration) [51]. In Li S et al.'s animal (ovariectomized rats) study, was also found that vitamin D deficiency was associated with deterioration of the knee articular cartilage, while the administration of 1,25(OH)2D3 with a protective effect on articular cartilage [52].

Vitamin D supplementation in patients with knee OA has been associated with a reduction in synovial membrane thickness and joint effusion associated with the OA development, as well as an improvement in knee articular cartilage architecture [53,54]. In a study of 413 women with symptomatic OA knee and low 25(OH)D, 209 women were supplemented with vitamin D (50,000 IU per os monthly) while 204 women were administered placebo for 24 months. This study investigates the effect of this administration on the articular membrane thickness and joint effusion using MRI. The rate of increase of the above-mentioned variables was lower in the group supplemented with vitamin D compared to the placebo group (risk ratio (RR)=0.87, 95% CI: 0.77-0.97) [53]. Veronese N et al. in 783 patients with knee OA (59.8% women, mean age 62.3 years), vitamin D supplementation was evaluated for its effect on the volume and thickness of the medial and lateral femoral condyle cartilage with MRI. Using linear regression analysis in which the effect of 10 potential confusing factors was assessed, it was found that vitamin D supplementation led to an increase in the volume and thickness of the medial and lateral femoral condyle cartilage, suggesting an improvement in its architecture [54].

Several studies have investigated the effect of vitamin D supplementation on joint pain, quality of life, physical function, joint stiffness, muscle strength (such as quadriceps femoris), joint space range, articular cartilage volume, and deficits as well as bone marrow lesions, etc, with conflicting results [55]. Moreover, in a systematic review and meta-analysis conducted in 2017, it was found to be small as a moderate result of vitamin D supplementation in knee pain [standardized mean difference (SMD)=-0.32, 95% CI: -0.63 to -0.02]. However, no effect was found on tibial articular cartilage volume/thickness (SMD=0.12, 95% CI: -0.05 to 0.29) or joint space range (SMD=0.07, 95% CI: -0,08 to 0.23). In other words, vitamin D supplementation had a rather favorable effect on knee pain but not on OA severity [56].

In all randomized controlled trials, 25(OH)D levels were found to increase in patients supplemented with vitamin D compared to patients that took the placebo. However, no reduction in pain (except for one study) or knee stiffness (evaluation with WOMAC scale) was found. On the other hand, in 2 of 3 studies that assessed knee pain using a visual analog scale (VAS), vitamin D supplementation led to an improvement in knee pain [57]. In Heidari B et al.’s study, 67 patients (aged ≥30 years with knee OA) received a supplement of 50,000 IU of cholecalciferol per week orally for at least two months. It was found that the cholecalciferol supplementation led to an increase in the normal level of 25(OH)D ($p=0.007$) as well as to a significant increase in quadriceps strength ($p=0.002$) and a significant decrease in knee pain ($p=0.001$) to all patients (except for one patient) [58].

In a multicenter randomized double-blind study, 340 patients with symptomatic knee OA were distinguished into one group of patients who received vitamin D (50,000 IU per month orally) and another group that received a placebo two years ago. The purpose of the above-mentioned study was the evaluation of this administration's effect on tibial articular cartilage volume, the presence of defects in tibial articular cartilage, bone marrow lesions, and knee pain. There was a significant increase in 25(OH)D levels in the supplemented group compared to the placebo group (40.6 nmol/L vs 6.7 nmol/L, $p<0.001$). However, no effect was found on tibial joint cartilage volume, the presence of tibial joint cartilage deficits, or bone marrow lesions as assessed by MRI [59].

Additionally, in a study of 175 patients with primary knee OA and low levels of 25(OH)D (<30 ng/mL), they were supplemented with 40,000 IU of vitamin D (ergocalciferol) per os once a week for six months. It was found significant increase in 25(OH)D levels ($p<0.001$), improved quality of life ($p=0.005$) and patients' functionality ($p<0.05$), as well as reduced knee pain ($p=0.002$) [60]. On the other hand, in a three-year double-blind, randomized study of 474 patients aged>50 years with radiological signs of knee osteoarthritis, it was found that the group of patients supplemented with vitamin D led to an increase at 25(OH)D levels compared to the placebo group, without affecting the narrowing of the joint space, pain, function, or stiffness of the knee joint [61].

The administration of high-dose vitamin D supplements has a rather beneficial effect on reducing knee pain. A meta-analysis of 4 randomized group studies with 1,136 patients, evaluated whether and to what extent the administration of a vitamin D supplement affects pain, function, stiffness, and tibial joint cartilage volume of patients with knee OA. It was found that this administration was associated with pain reduction and improved function but did not improve knee stiffness or tibial joint cartilage volume. Particularly favorable was the effect on pain and knee function in patients receiving a dose of natural vitamin D higher than 2000 IU [62].

It was also studied whether vitamin D supplementation and maintaining adequate levels affected inflammatory markers and metabolic biomarkers associated with OA pathogenesis. Zheng S et al. studied 413 patients with symptomatic knee OA and vitamin D deficiency, who were randomly assigned to one group receiving 1.25 mg of vitamin D3 and to another group receiving a placebo, once a month for 24 months. The researchers concluded that vitamin D supplementation as well as maintaining adequate levels did not affect inflammatory markers or metabolic biomarkers [63].

CONCLUSIONS

In conclusion, low levels of vitamin D in patients with OA rather adversely affect the structure and function of articular cartilage. They are associated with joint pain, limited physical activity, quality of life, etc, as well as decreased muscle strength, primarily of the lower extremities with adverse OA progression. A high percentage of low vitamin D levels was found in patients with OA and joint arthroplasty as well as less satisfactory postoperative progress in patients with these low levels. The administration of vitamin D supplementation in patients with knee OA has been associated with improved articular cartilage architecture and reduced joint pain in combination with improved function and quality of life.

REVIEW

Biotribology of the Total Hip Replacement – Review of the Current Bearing Surfaces

Abstract: *Total hip replacement surgery (THR) is one of the most common surgeries performed in modern orthopedics, and in most cases offers a significant improvement in the quality of the patient's life. However, after some time, wear and osteolysis do appear, which leads to the need for revision surgery. With the indication being widened to a more young and active population, the need for extending the lifespan of the prosthesis is mandatory. Although several bearing surfaces have been studied over the years, and a lot of couplings are in use, the choice of the right combination of materials is still controversial. Biotribology tries to answer some of the current questions regarding the best bearing surface to use, being the branch of science and technology that studies friction, wear, and lubrication of different materials in the human body. In the present day, a large number of materials are in use for total hip replacement, but choosing the right combination of materials is still controversial, and is being done on one hand by the surgeon's experience and on the other hand by the age and activity of the patient. The objective of this review is to try to present the main advantages and disadvantages of different materials and try to answer the most difficult question of them all: What is the right material to use for THR-bearing surfaces?*

Keywords: *total hip replacement, tribology, biotribology, arthroplasty*

INTRODUCTION

More the 350,000 total hip replacements are done each year in the United States [1], with a constantly increasing rate. The survival rate of these implants is, according to the British National Joint Registry, 93.2% at 13 years, and 80% up to 20 years [2]. Although these rates seem to be pretty good, about 13% of these hip replacements are revision arthroplasties [3]. This high rate can be attributed to the younger and more active patients who were treated with this procedure.

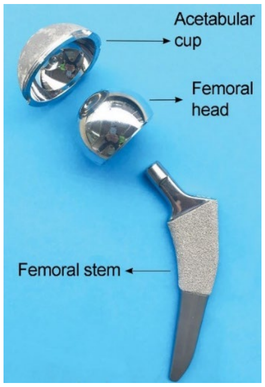
The most important aspect is still worn, which limits the lifespan of this prosthesis to 10 – 15 years. With a lot of materials and couplings to choose from, such as hard-on-soft bearings like metal-on-polyethylene (MoP) and ceramic-on-polyethylene (CoP), and hard-on-hard bearings such as ceramic-on-ceramic (CoC), metal-on-metal (MoM) and ceramic-on-metal (CoM), it can be confusing for both the patient and the physician, all of these materials showing specific wear mechanisms and characteristics that will be discussed in the present paper. Wear patterns like burnishing, abrasion, pitting, and scratches were observed for ultra-high molecular weight polyethylene (UHMWPE) and cross-link polyethylene (XLPE) [4], stripe wear was observed for ceramic components [5], changes in surface characteristics like roughening and roundness for metal-on-polyethylene couplings [6], gouging, scratching and polishing for metal-on-metal couplings [7].

Metal-on-metal couplings

With the first implantation in 1938 by Wiles, the MoM coupling was the first bearing used for THR. In conventional metal-on-metal hip replacements, the prosthesis is made up of a large diameter metallic femoral head on a standard femoral stem that articulates with a metal acetabular cup or liner, CoCrMo alloy was used widely for these bearings (Figure 1).

The advantages of this type of coupling are that they could be engineered to be extremely smooth and hard, properties that can reduce the wear rate, and the wear rate of MoM is estimated to be 60 times less than conventional MoP implants [8]. Other advantages include increased resistance to dislocation associated with large-diameter heads and reduced osteolysis due to the absence of polyethylene particles [8].

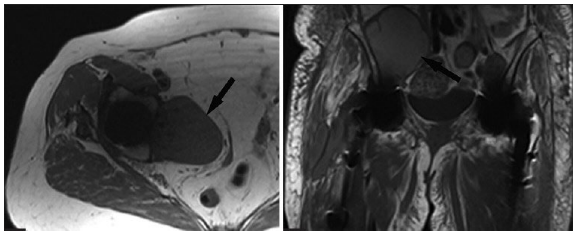
Figure 1: Metal on-metal coupling [10]



On the other hand, MoM materials come with a series of disadvantages. The metal alloys used in orthopedic implants degrade due to wear and, unlike polyethylene, also corrosion. This can lead to soft tissue inflammatory reactions to metal debris, known as adverse reactions to metal debris. The rate of wear depends largely on the contact force between the two surfaces and the sliding distance, and thus increases with physical activity, weight gain, larger implants, and the roughness of the implant surface [9].

The **inflammatory pseudotumors** (Figure 2) represent the existence of an aseptic mass in the periprosthetic tissue that can be solid or cystic and associated with local inflammation [11]. It is believed that it develops as a result of an adverse reaction to the metal ions released from the wear of metal articular bearing surfaces [12]. Implanting the acetabular cup at abnormal inclination angles increases the edge loading which leads to increased prosthetic wear [13]. The incidence of pseudotumors is up to 32% in some studies [14]. In a study conducted in 2009 on 1224 patients, it was shown that female patients and those under 40 years of age had an increased risk of revision due to pseudotumors [15].

Figure 2: The inflammatory pseudotumors [16]

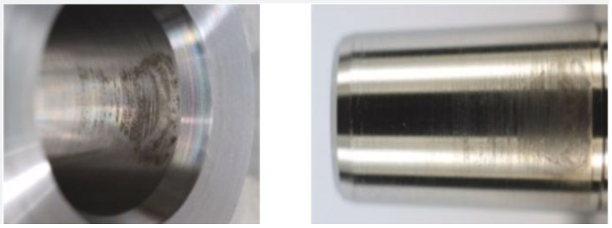


Aseptic lymphocytic vasculitis-associated lesion (ALVAL), consists of cellular changes that occur as a response to cobalt and chromium ions. The mechanism is believed to be a T lymphocyte-mediated type 4 hypersensitivity reaction, with tissue damage occurring as a result of cytotoxic T cells and activated monocytes/macrophages].

Metallosis, represents aseptic fibrosis, local necrosis, or aseptic loosening of a device because of metallic corrosion and release of wear debris [18].

Trunnionosis (Figure 3), the metal wear at the head-neck junction of a total hip implant is believed to be an important contributor to the release of metal particles [19]. It is present in the modular design prosthesis, both in MoM and MoP, because in both cases the head-neck junction is made up of metal-on-metal surfaces. This is the main reason why trunnions cannot be blamed to be the only cause of the increased rate of adverse reactions in MoM hip replacements.

Figure 3: Trunnionosis [20]



Revision rates for MoM at 10 years for cemented and uncemented hip replacements are 19.68% and 21.92% by comparison with MoP, which was 3.13% and 3.98% [21]. There seems to be a direct connection between the size of the femoral head that was used and wear, in THR that used a head size above 40mm the revision rate at 10 years was 25.5%, by comparison to those that used a femoral head diameter below 28mm with a revision rate at 10 years of just 5.7%.

Serum and urine ion levels produced by MoM bearings are similar to the ones produced by the modular junctions of femoral components. The toxicologic importance of these trace metal elevations has not been established. Because the wear of a THR with an MoM bearing cannot be evaluated radiographically, metal ion concentrations in serum and urine can be indicators of wear [22].

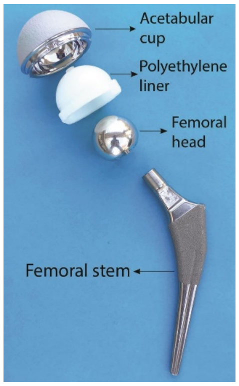
Considering the renal excretion of Co-Cr ions, a potential for increased risk of bladder and other cancers in patients with metal-on-metal couplings was formulated. Two large studies were conducted in England and Wales and Finland that examined nearly 330.000 patients [23,24], but no connection between MoM bearings and the high risk of developing a type of cancer was discovered. The follow-up protocol within those studies was seven and four years. So, we think that studies with a longer follow-up period are needed to completely declare that MoM implants do not increase the risk of cancer development.

Due to all of these considerations, in the present day, the MoM THR is almost entirely abandoned by surgeons and withdrawn from the market by manufacturers [25].

Polyethylene

Conventional and cross-linked polyethylene liners are the most common choice in THR. First used by Charnley in 1962 [26], this polymer is a high molecular weight polyethylene with extremely long chains. Until the mid-2000s, the MoP bearings (Figure 4), with head diameters between 22 mm and 32 mm we're considered the standard. The linear wear for PE is between 100 to 300 µm/year [27], which corresponds to volumetric wear of 20 – 150 mm^3/year for 28 mm heads [28]. It was shown that a correlation exists between volumetric wear and the risk for osteolysis, every increase in the amount of volumetric wear of 40 mm^3/year triples the long-term risk of osteolysis [29].

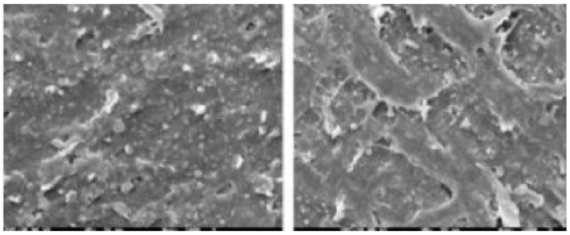
Figure 4: Metal on polyethylene coupling [10]



When using polyethylene liners, not only the material is important, but also the sterilization technique, because this too can influence the mechanical properties and biological effects. The most common sterilization method used was gamma irradiation. Some studies [30] show that this sterilization method increases cross-linking between polyethylene molecules offering a more wear-resistant material. But, when this is done in the presence of oxygen, free radicals are released that can oxidate and make the liner more brittle with reduced resistance and increased wear. So, thermal sterilization with gas plasma was shown to improve wear and oxidation resistance [30, 31], and oxygen-free gamma irradiation showed less head penetration and less osteolysis [32].

Because of the wear debris of the conventional polyethylene, cross-linked polyethylene was developed (Figure 5). It is obtained by irradiation of conventional polyethylene with at least 50 kGy of gamma beam radiation, which induces the cross-linking between PE molecules, which increases wear resistance [33]. The rate of revision at 16 years for XLPE was 6.2% vs. conventional PE which was 11.7% [34]. The process of cross-linking can however decrease the mechanical properties so that the liner can become at risk for fatigue fracture because the irradiation process releases free oxygen radicals [35]. In addition, steep positioning of the acetabular cup leads to stress concentration or impingement and it is considered also a risk factor [36]. This problem was solved by introducing vitamin E into the liners, which is an antioxidant, and the mechanical properties are saved. Also, the liners can be now thinner and the femoral head bigger, which can improve joint stability.

Figure 5: Cross-link polyethylene–electron microscopy [37]



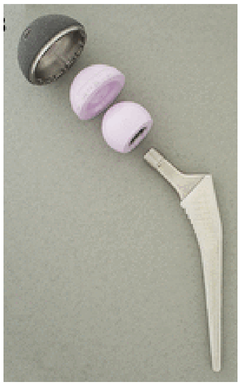
When evaluating the long-term resistance of PE, conventional or cross-linked, we must take into consideration also the femoral head material and diameter. We know that the larger the femoral head diameter the bigger the wear, especially when coupled with conventional PE [38]. It seems that this does not apply to XLPE, where the wear rate is not higher for bigger head diameters [38].

In the matter of ceramic vs. metallic femoral heads, in early studies, the average wear rates with the metal femoral head (stainless steel and cobalt chrome) invariably were higher than with ceramic femoral heads [39-41]. In a more recent study based on a systematic analysis of registry data, an overall equal long-term performance was found between metal and ceramic heads, although a lower revision rate was discovered with CoXLPE than MoXLPE [38]. The advantages of ceramic heads are higher hardness with less risk of damage during implantation, the surface finishing with only negative peaks due to grains detachment rather than deformation, and higher wettability which means better lubrication of ceramic, less friction and scratching and less linear wear [27]. Last, but not least, alumina is biologically inert and has the best biocompatibility.

Ceramic on ceramic

Alumina and zirconia ceramic is used in THR surgery (Figure 6). Alumina has a very low friction coefficient, is biocompatible, and its material properties are not affected by aging it was also shown that it reduces volumetric wear [33]. With the risk of fracture being the most severe concern, alumina (82%) was mixed with zirconia (17%), chromium oxide (0.5%), and strontium crystals, and a higher resistance to crack and enhanced hardness were obtained. With this breakthrough, the fracture rates of the femoral head were reduced from 0.021% to only 0.003% [42]. However, the risk of ceramic head fracture is still lower than the risk of ceramic liner fracture (0.003% vs. 0.03%) [43]. The survival rate at 10 years of these implants in excellent, varying from 98% to 99.3% [44], 92.8% at 15 years [34], and 84.4% at 21 years [45].

Figure 6: Ceramic on ceramic coupling [46]



The advantages of CoC bearings are a very low friction coefficient and very low wear rates, due to high wettability and hardness. If however, the ceramic implant does suffer wear, the particles released are biologically inert and produce a less biological reaction. Another great advantage is that the wear is not dependent on the diameter of the femoral head, a large femoral head will provide a more stable artificial joint with a low risk of dislocation. A recent study showed that 36mm ceramic femoral heads had a lower revision rate than smaller 28mm ceramic femoral heads [47]

Like any other bearing surface, the CoC coupling also has a series of drawbacks. Although the risk of fracture was lowered as presented, the risk remains and is a catastrophic complication that requires revision surgery. Factors that can increase the liner fracture risk are misalignment during insertion of the liner, metal back damage or acetabular component malposition that can lead to edge loading, and the most important factor, excessive anteversion.

Another disadvantage is the noise that this coupling can produce. Clicking, grinding, clunking, and squeaking has been described. The incidence varies from 0.7% to 20.9% [48], this adverse event can even be a cause of revision, with a rate of 0.2% [49]. Risk factors for squeaking are age, obesity, activity level, soft tissue balancing, and positioning of the acetabular cup.

It is recommended that in cases with severe posttraumatic acetabular deformities or severe developmental dysplasia of the hip, the CoC should be avoided, because of the difficulty of correct positioning of the acetabular component.

Another drawback of the CoC bearing is the cost. It is the most expensive choice of coupling, but also the most advanced and resistant to wear when used correctly.

DISCUSSION

After the literature data has been analyzed, we concluded that the preferred choice when it comes to total hip arthroplasty bearings is a hard-on-soft coupling like the metal (cobalt-chrome) on polyethylene or ceramic on polyethylene. MoPs are still the most widely used coupling covering about 60% of all interventions, but the use of CoP is increasing. But which of the two is better?

If we consider the studies of wear screening using water-based lubrication and linear tracking, there is a 20-to-80-fold advantage for ceramic-on-polyethylene when compared with metal-on-polyethylene [50]; however newer wear studies with high protein concentrations have shown similar wear with alumina or with met-al-on-polyethylene [51]. Because of the biological advantages of alumina which is biologically inert and with the amount of literature that supports the superiority of the ceramic femoral head, we too recommend the use of ceramic-on-polyethylene bearings over the metal-on-polyethylene ones.

Considering the type of polyethylene that should be used, we feel that is enough literature that proves that conventional polyethylene has a much higher wear rate than cross-link polyethylene. More and more manufacturers are offering just the cross-link version now, the only advantage of the standard polyethylene is the lower cost of production. However, we feel that because of the high wear rate that requires early revision, there is practically no cost advantage, and therefore we cannot recommend using conventional polyethylene anymore.

How about hard-on-hard surface bearings? We know that the manufacturers do not provide the MoM bearing anymore, due to the pseudotumors caused by toxic metallic ions, so the only valid option for this kind of bearing is the CoC.

Although the wear is insignificant with this coupling and is not associated with femoral head diameter, there is still concern about motion sounds like squeaking, which has a revision rate that varies between 1 and 21%. Another drawback is the risk of liner fracture; although is a quite low risk, it has a catastrophic impact and requires urgent revision surgery. So, there is still room for improvement.

CONCLUSIONS

Deciding what coupling to choose is mostly dependent on the surgeon's preference and experience. Considering the literature mentioned in the present paper we recommend the use of CoC bearing if the cost is not an issue, in young and high-activity demanding patients, with a large diameter femoral head, up to 36 mm, as wear is not related to large head diameter femoral heads and can improve joint stability. Care must be taken in cases where the correct positioning of the acetabular component may be an issue, as the malposition of the acetabular cup can lead to squeaking and increase the risk of fracture of the ceramic liner.

CoXLPE is a good option for CoC, with a lower cost and offers comparable results. It can be successfully used in active patients over 60 years of age, care must be taken in choosing the right femoral head, larger diameter head being associated with a higher wear risk. We cannot find any reason for using conventional PE, as it proved to be less reliable and more susceptible to wear, with a higher risk of releasing debris.

The choice of MoXLPE remains a viable option in a situation in which cost is an issue. Other than cost-related issues, the ceramic bearings are a more reliable option over the metallic on PE.

Even if the best bearing surface is available, we should not forget that coupling is not everything, and careful patient selection is still mandatory. More than that other factors influence the overall behavior of the THR, like age, level of activity, anatomic deformities of the acetabulum, positioning of the components, bone quality, soft tissue balancing, and patient compliance. So, to have a successful THR all of these factors must be carefully quantified, and the surgeon must use the correct surgical technique.

Abstract: *A successful nose reconstruction is represented by a normal look and nasal breathing preservation. The choice of method is based on the site, size, depth of the defect, donor availability, and surgeon experience. There are multiple methods of restoring nasal cover, from primary repair to healing by secondary intention, from primary suture, skin graft to locoregional flaps, but all of them should be integrated into a personalized approach, keeping the nasal functions, a good aesthetic outcome and without any tumor infiltration. This paper consisting of a retrospective study of 9 patients diagnosticated with squamous cell carcinoma revealed the importance of skin properties and skin changes during aging. Despite all aesthetic principles, skin is the most important resource in facial reconstruction.*

Keywords: *nose reconstruction, aesthetic, squamous cell carcinoma*

INTRODUCTION

Cutaneous squamous cell carcinoma is one of the most common skin cancer with an increasing incidence [1]. Most frequently on sun-exposed sites, like the face, it could be a challenge for a surgeon [2]. One, because of its aggressiveness and the possible requirement of large excisions, and second, because of the psychological impact on the patient. The nose is one of the most visible anatomical sites so, an aesthetic result is even more required. The nasal restoration should be based on keeping the contouring, color, and texture, minimalizing the scars, and preserving the breathing function [3].

MATERIALS AND METHODS

A retrospective study performed in the Plastic Surgery Department of Emergency University Hospital, Bucharest, Romania evaluated 9 patients diagnosticated with cutaneous squamous cell carcinoma at the nose level through the histological exam, two of them with local relapse. The age average was 63 years old, with a minim of 44 years old and a maxim of 90 years old. It was identified as a male prevalence.

In all cases, the tumor resection was performed with free macroscopically oncological edges. Depending on the tumor size, site, and patient age, multiple reconstruction techniques were required. In 4 cases primary suture was practiced, in 3 cases local flaps were required, and in 2 cases skin grafts.

All the patients signed the Informed Consent before surgery and the study was approved by Ethics Committee.

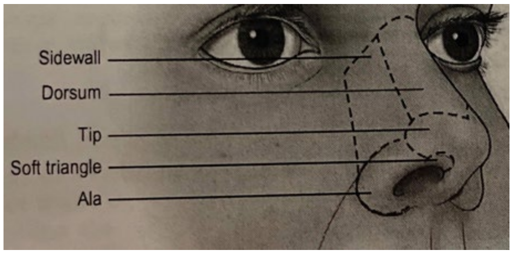
DISCUSSION

There are nine aesthetic subunits of the nose, dorsum, paired sidewalls, nasal tip, paired alae, columella, and paired soft tissue facets (Figure 1). The concept of aesthetic units in nasal reconstruction was first described by Millard to improve surgical results. Then, Burget and Menick introduced the principles of nose aesthetic subunits which improved the aesthetic results in nose reconstruction [4].

The skin quality is different in every aesthetic subunit, being thicker at the nasal tip, nasal alae, and cranial dorsum, and upper nasal sidewall and mid-lower dorsum being the thinnest. In all facial reconstructions, the skin patient is an important factor. During aging, the skin properties are changing and the skin becomes looser.

Nose reconstruction is a complex process in which the first step should be defect identification. A classification of nasal defects is based on size. There are small defects, with a diameter of less than 1.5 cm, and large defects, with a diameter over 1.5 cm, which require a skin graft or a local flap [5].

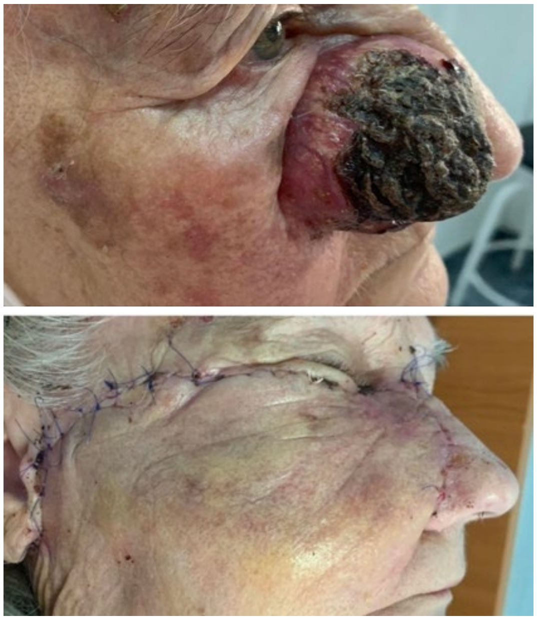
Figure 1: Nose aesthetic subunits



Depending on the depth of injury, there are superficial defects where the skin is missing and also, a small underlying subcutaneous fat and nasalis muscle could be missing. Deep defects are represented by the absence of an underlying supportive framework or lining. The cartilage could be affected, so a composite skin graft could be required, cartilage grafts, or vascularized regional flap for cover [6].

A more complex reconstruction is required by composite defects which are represented by nose defects extended to the cheek or upper lip (Figure 2). The challenge consists of the fact that they are different aesthetic units. The reconstruction of composite defects should be based on keeping the quality, outline, contour, projection, and function of each one, not only to “fill the hole”.

Figure 2: Nasogenian tumor that left a composite defect including sidewall, ala, dorsum, and cheek, which was covered by a local cheek flap



Choosing the reconstruction method should be based on the shape, size, location, and depth of the defect and the aesthetic unit involved [7]. The bilobed flap is one of the most common local flaps used in nose reconstruction, especially for tip and ala defects, when the diameter of the defect doesn`t count more than 1.5cm [8]. The Bipedicle mucosal flap could be useful in small alar reconstruction to keep the lining of the nose [9].

Another common flap in nose reconstruction is the septal hinge flap which is used for tip, ala, and sidewall defects [10]. The technique is based on the anterior septal artery. When the nasal tip and columella are missing, and also a part of the septum, bilateral septal flaps could restore the lining of the ala and nasal vestibule [11,12,13].

In cases of full-thickness defects, especially for lateral defects, the inferior turbinate flap could be a good option, alone or together with other techniques [14].

Forehad flap is useful for any significant nasal defect over 2.5 cm. It can be also used when the septal hinge flap and inferior turbinate flap failed. The technique is based on the supratrochlear vessels that pierce the orbital bone at about 2 cm lateral to the midline [15].

Melolabial flap in an interpolated flap is used for defects less than 4 cm, especially for cutaneous nasal ala defects with or without modest extension into the tip and sidewall [16].

The aesthetic outcomes between local flaps and skin grafts are depending on patients' selection. Sapathavee, Munaretto, and Toriumi proved that a skin graft provides an aesthetic result in patients with Fitzpatrick types 1 and 2 skin, also with thin and less sebaceous skin. The preauricular skin offers a good match in nose reconstructions. Some authors are using “skin fat grafts” to fill small deep defects of the nose [17].

Keeping the structure of the nose is an important part of the reconstruction. Cartilage grafts are useful tools in maintaining nose support. They prevent also overlaying soft tissue contraction, minimize pincushion deformity and reduce nasal obstruction. The donor sites could be costal cartilage or calvarial bone for restoring the contour and support of total or subtotal nasal defects, and conchal cartilage for alar reconstruction due to its curvature shape.

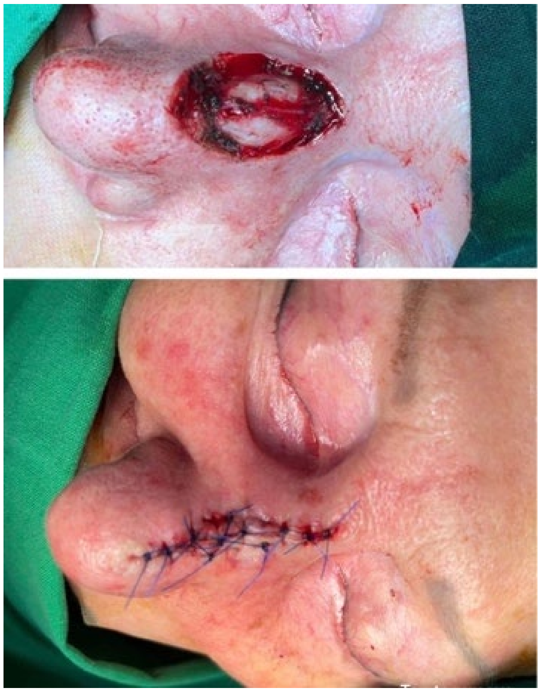
To keep the internal lining, a composite graft from the conchal site could be used. Also, a composite graft from the helix root could be used in nasal ala restoration [18].

In our case, we used skin grafts in 2 cases of female patients, about 63 and 69 years old. The tumors had the same localization, at the dorsum level, and has a diameter over 3 cm, without bone invasion.

In 2 cases of the cutaneous tumor with approximately 1.5 diameters, at the sidewall and ala levels, local flaps were performed. The nasolabial transposition flap was the reconstruction method for ala defect, while for sidewall defect a dorsal nasal flap was performed. Rieger described the dorsal nasal flap as a laterally-based rotation flap with a wide pedicle. The technique consists in designing a "V" in an upside-down fashion over the glabella and then a curvilinear line on the nasal–cheek junction till it reaches the defect site. Marchac and Toth updated the Rieger version by narrowing the pedicle in an axial flap based on the vessel arising from the inner canthus. The advantages consist in increasing mobility, decreasing wound closure tension, and a more precise adjustment [19].

One case of a cutaneous tumor involving multiple nasal subunits, with a diameter over 4 cm, without bone invasion, required multiple techniques of reconstruction, frontal flap for dorsum defect, and primary suture for secondary defects.

Figure 3: Intraoperatively picture with dorsum defect size after squamous carcinoma resection for which the skin allowed a primary suture.

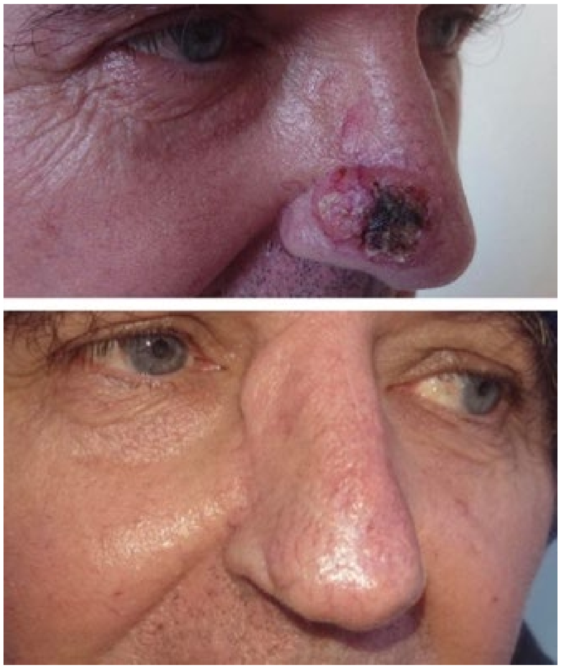


In 4 cases, the primary suture was enough for closing the defect. Three of them had a diameter less than 1.5 cm, one at ala level and 2 at dorsum level, with ages between 59 and 80 years old. There was another case of 77 years old female, with a diameter tumor of approximately 2.5 cm at the dorsum level, for which the primary suture was enough (Figure 3). Usually, a defect of 2.5 cm isn`t suitable for primary suture and a local flap is mandatory. For defects of 1.5 cm – 2.5 cm, a dorsal nasal flap, a bilobed flap, or a glabellar flap could be used [20].

So, depending on the aesthetic unit involved and defect size, nasal reconstruction methods differ. Choosing the reconstruction method should be based on restoring the aesthetic unit, not on filling the defects. Keeping a natural look, the borderline, the skin quality, and preserving the breathing function are variables that we should take into account in nose reconstruction, but free tumor edge is the most important medical approach. Dorsum and sidewalls have common skin characteristics, so the reconstruction methods are similar. Defects less than 1.5 cm could be closed primarily, with a glabellar flap or a transposition one. Defects with a diameter of 1.5-2.5 cm require a local flap, a glabellar flap, a bilobed flap, or a dorsal nasal flap. The last one can be also used for defects more than 2.5 cm [21].

In case of nasal tip defects, a bilobed flap can be used for defects less than 1.5 cm, a dorsal nasal flap under 2.5 cm, and forehead flaps for defects of or bigger than 2.5 cm (Figure 4).

Figure 4: Skin tumor involving ala unit which required a forehead flap



In case of nasal ala defects, a full-thickness skin graft and a cartilage graft to keep the shape and to avoid breathing obturation is a good choice for superficial defects, while in case of deeper defects, a more complex reconstruction like nasolabial flap or interpolated melolabial flap is required [22].

Despite all the reconstruction science of skin defects, skin properties are changing during aging which requires a personalized surgical approach.

Even if the resection was performed with free macroscopical tumor edges, the histological exam revealed a deep tumor infiltration in 5 cases, which showed the limitation of anatomical site between safe tumor resection with free tumor edges and aesthetic result.

CONCLUSIONS

Since the nose is the most visible part of the body, its reconstruction has an important role in the life quality of patients. Behind the science, plastic surgery is also about art and understanding that skin suffers changes during aging which affects its properties, its structure and requires a personalized approach. Every nose reconstruction should be based on keeping a three-dimensional contour, keeping the quality of the skin, the border outline, and breathing function. All the techniques should be focused on restoring the aesthetic units, not on filling the defects. Sometimes the preservation of the aesthetic aspect interferes with the preservation of nose function and complete resection of the tumor, which is a challenge for the doctor to make the patient understand the prioritization of health over the aesthetic aspect and to help him to manage this situation without decreasing quality of life.

Conflicts of interest and sources of funding

The authors declare no conflict of interest.
This research received no external funding.

Authors' contribution

A.G. conceptualization and writing (original draft preparation), A.M.O. methodology and writing (review and editing), I.P.F. data curation and supervision. All authors have read and agreed to the published version of the manuscript.

Ethics approval and consent to participate

Approval of the local Ethics Review Board of Emergency University Hospital of Bucharest was obtained for the use of the patient data.

Patient consent for publication

Informed consent was obtained from all subjects involved in the study

Abstract: *Background: It is well known that patients with polycystic kidney disease (PKD) are at increased risk of developing cerebral aneurysms, however, this association has not been well studied for patients with polycystic liver disease (PLD). Material and methods: Cross-sectional descriptive study, which included 15 adult patients diagnosed with polycystic liver disease at the Gastroenterology and Hepatology Department of Fundeni Clinical Institute. Standard neurological exam and brain MRI were performed in all patients on a 1.5 Tesla MRI. Brain imaging protocol included T1/T2, T1SE, T2-FLAIR, DWI, SWI, 2D-TOF, 3D-TOF. Results: The majority of patients (93%) were females. The mean age was 53 ± 5 years old. Patients with AD-PKD and polycystic hepatic disease predominated (60%). Aneurysms were found in only one patient diagnosed with AD-PKD (in whom three aneurysms were described). The overall prevalence of cerebral aneurysms in our patient group was 7%. However, none of the patients with isolated PLD was found to have intracranial aneurysms. Other brain imaging abnormalities were frequent but nonspecific (mostly attributable to vascular-degenerative changes). Conclusions: Given these results, and due to the small number of patients in our study, it is hard to appreciate if polycystic liver disease is indeed associated with an increased risk of cerebral aneurysms.*

Keywords: *polycystic liver disease, cerebral aneurysm, brain MRI*

INTRODUCTION

Polycystic liver disease (PLD) is a genetic disorder characterized by the replacement of normal hepatic tissue with fluid-filled cysts. This is due to genetic mutations of the proteins that are involved in epithelial growth and transport of fluid in the liver [1]. Some authors have defined PLD by the presence of more than 10 cysts in the liver, while others have defined it as a liver containing over 20 cysts [2,3]. PLD can occur in isolation or can be associated with autosomal dominant polycystic kidney disease (AD-PKD), in which case patients present with cysts involving both the liver and the kidneys.

The latter combined form (AD-PKD and PLD) is more common, accounting for 80-90% of all patients with multiple liver cysts [4]. It is well-known that patients with PKD are at an increased risk of developing cerebral aneurysms [5,6], however, this association has not been well-studied for patients with PLD.

MATERIALS AND METHODS

We performed a cross-sectional descriptive study, in which we recruited 15 adult patients diagnosed with PLD at the Gastroenterology and Hepatology Department of Fundeni Clinical Institute. All patients were included on the liver transplantation waiting list (or have already benefited from liver transplantation). The evaluation comprised a standard neurological examination and electroencephalogram. Brain MRI was performed in all patients on a 1.5 Tesla MRI. Brain imaging protocol included T1/T2, T1SE, T2-FLAIR, DWI, SWI, 2D-TOF, 3D-TOF. To better characterize PLD, abdominal CT scans with contrast enhancement and volumetric assessment of the liver were performed in all patients. Laboratory workup included liver function parameters (albumin, total bilirubin, conjugated bilirubin, alkaline phosphatase, gamma-glutamyl transferase, alanine aminotransferase, aspartate aminotransferase, ammonia, blood coagulation tests), kidney function parameters (urea, creatinine, uric acid), complete blood count, inflammatory markers and tumoral markers (alpha-fetoprotein, CA 125, CA 15.3, CA 19.9, CEA). Liver disease severity was measured using the MELD score, while kidney function was measured using serum creatinine levels and creatinine clearance (Cockcroft-Gault Equation).

Patients were included only if an informed consent form was signed and if the inclusion and exclusion criteria were respected (see Table 1). The study protocol was approved by the Ethics Committee of Fundeni Clinical Institute.

Table 1: Inclusion and exclusion criteria used for patients in our study.

Exclusion criteria	Inclusion criteria
Patients diagnosed with other cystic lesions of the liver (e.g., Caroli disease)	Age > 18 years-old
Patients diagnosed with isolated polycystic kidney disease	Diagnosis of polycystic liver disease ± polycystic kidney disease

Relevant medical information (imaging results, laboratory test results) was accessed using the hospital's informatic system Hipocrate. The patient database was created with Microsoft Office 365.
